THE CARNEGIE MAYA IV

CARNEGIE INSTITUTION OF WASHINGTON
THEORETICAL APPROACHES TO PROBLEMS, 1941-1947

COMPILED AND WITH AN INTRODUCTION BY
JOHN M. WEEKS

How to go to your page

This eBook contains four volumes. Each volume has its own page numbering scheme, consisting of a volume number and a page number, separated by a colon.

For example, to go to page 5 of Volume 1, type 1:5 in the "page #" box at the top of the screen and click "Go." To go to page 5 of Volume 2, type 2:5... and so forth.

PREFACE

This volume includes approximately 360 authored reports pertaining to the ancient and modern Maya and submitted by a variety of researchers from the Carnegie Institution of Washington (CIW) between 1913 and 1958. Originally published in the annual *Year Books* of the Carnegie Institution of Washington, these reports provide basic information about the ancient and mid-twentieth-century Maya people of the southern Mexican states of Campeche, Chiapas, Quintana Roo, Yucatán, and the parts of Tabasco and Veracruz, as well as Belize (British Honduras), Guatemala, and the western parts of Honduras and El Salvador (Figures 1 and 2). Although much of the material has been presented in formal monographs, most of these monographs have a highly limited distribution and there still remains much information never published outside the *Year Book* series. We seek to remedy this situation because not only are the reports presented in this volume interesting in their own right as archaeological research, but more importantly they document the accomplishments and achievements of

the most significant anthropological project ever undertaken to examine a single anthropological or archaeological region.

One result of the CIW Maya program was the development of the standard image of Maya civilization, one that overwhelmingly emphasizes the activities and achievements of the upper class. As promoted vigorously by Sylvanus G. Morley and J. Eric S. Thompson, the Maya as people *sui generis* were believed to be extraordinarily spiritual, knowledgeable priests, unconcerned with material matters in a life without wars; a people of philosophers and astronomers. The image was of a series of elaborate ceremonial centers, each supported by an extensive slash-and-burn agricultural system. The principal inhabitants of these centers were the kings and priests and their retainers. The farmers lived scattered around the nearly vacant centers. The privileged concentrated on intellectual and religious concerns, carved monuments with esoteric content, and lived relatively peaceful existences. The farmers supported the residents of the centers with food and were

mobilized by the rulers for occasional large construction projects. In return, the priests interceded with the deities to provide an orderly world with predictable rain and abundant crop yields. Archaeologists emphasized not only the elite aspects of ancient Maya society, but also the Classic period in the Petén lowlands of northern Guatemala and in adjacent Belize and Mexico. It was here that the major settlements were located.

Since the closing of the CIW Maya program, research in southern Mesoamerica and northern Central America has increased in frequency, scope, and significance. Universities are now primary sponsors of archaeological, linguistic, and ethnographic research in the Maya region. This research has resulted in major revisions to the scholarly understanding of Maya civilization. New studies of hieroglyphic inscriptions and breakthroughs in decipherment have detailed the history of previously anonymous Maya rulers and their interactions. These inscriptions have revealed a political landscape of the Maya lowlands indicating that the Maya world was not peaceful, but strained by endemic warfare.

The current scientific vision of the ancient Maya is the result of new methodological approaches in archaeology, epigraphy, iconography, history, history of religions, history of art, physical anthropology, and linguistics, which have been integrated into interdisciplinary projects along with other scientific fields, such as biology and astronomy. An increasing willingness by archaeologists and other scholars to contextualize their research within more sophisticated theoretical and methodological constructs as a result of improved academic training in anthropology has produced an emerging understanding and appreciation of the nature and magnitude of Maya civilization.

But it is only fair to recognize that these approaches are firmly rooted in the work of the CIW Mayanists. Our greatest debt is to the archaeologists, ethnographers, linguists, ethnohistorians, and other researchers of the CIW who provided the information published in this volume. The CIW Maya program in southern Mesoamerica is no more; it has been modified, expanded, and replaced by several generations of new scholars. Its legacy, however, stands as a firm foundation upon which an entire field of study was based.

During the course of assembling this volume, we have had the good fortune to find many individuals

who enthusiastically have supported this project. Grateful acknowledgment is made to Ms. Patricia Craig and Ms. Tina McDowell at Carnegie Institution of Washington headquarters in Washington, D.C., for granting permission to reprint the contents of this volume.

The support of Mr. H. Carton Rogers, Vice Provost and Director of Libraries, University of Pennsylvania Libraries, and Dr. Richard M. Leventhal, Williams Director, University of Pennsylvania Museum of Archaeology and Anthropology, are acknowledged with thanks. The facilities and collections at the Museum Library and the Van Pelt–Deitrich Libraries at the University of Pennsylvania have been a continuing source of relevant material and essential services.

At the Peabody Museum of Archaeology and Ethnology, Harvard University, Ms. India Spartz, Senior Archivist, and Ms. Patricia H. Kervick, Associate Archivist, provided us with an updated version by Victoria H. Swerdlow and Sarah R. Demb of the collection description for the archaeological archives of the Carnegie Institution of Washington.

Dr. Christopher Winters, Bibliographer for Geography, Anthropology, and Maps, University of Chicago Libraries, helped us to obtain a complete inventory of field notes for ethnographic and linguistic studies by Robert Redfield, Sol Tax, Manuel J. Andrade, and Norman McQuown, reproduced in the *Manuscripts on Middle American Cultural Anthropology*, *Manuscripts on American Indian Cultural Anthropology*, and *Microfilm Collection of Manuscripts on Cultural Anthropology*.

At the University Press of Colorado, Darrin Pratt, Director, undeterred by the size of the manuscript, has ably guided this volume through its development from a concept, through a manuscript, and finally, as a published book. As our editor, he caught numerous problems and brought them to our attention.

We appreciate the support and, at times, feigned curiosity about the project from Greg Borgstede, Elin Danien, Charles Golden, Christopher Jones, Simon Martin, Sharon Misdea, and Jeremy A. Sabloff.

Mary Ricketson Bullard, Padanaram, South Dartmouth, Massachusetts, sparked the idea for this volume thirty years ago during a drive from Guatemala City to the ruins of Zaculeu, Department of Huehuetenango, in northwestern Guatemala. This book is for her.

INTRODUCTION

Between 1914 and 1958 the Carnegie Institution of Washington (CIW) sponsored extensive archaeological and other investigations in the Maya region of southern Mexico and northern Central America. During these four decades, the CIW was the leader in the field, with monetary and human resources that no university or other research program could match, then or since. The more than 300 publications produced by CIW researchers remain an important, indeed essential, resource for modern scholars. Some, however, have characterized the CIW program as barren and narrow, without any real anthropological purpose. Although there is some truth to such harsh critiques, these criticisms miss the essential contribution of the CIW. From its beginning, the program was designed to study a single civilization in its entirety from a variety of perspectives. This research produced significant results that have had an impact unmatched by more recent efforts.

Information about the inception, progress, and results of various CIW-sponsored research programs was published annually in the CIW's *Year Books*. Each

annual report followed a standard format. An introductory essay prepared by the chair of the Historical Division summarized the general activities and accomplishments of the past year. This essay was usually followed by a series of authored reports on a variety of specific research projects. A final section would detail recent CIW monographs or other series, followed by a bibliography of publications by CIW researchers. These reports are remarkable for a number of reasons. They often provide detailed justification for projects and permit the reader to monitor the development of a research concept or direction. Many reports provide detailed information and primary data that was not subsequently published in other formats. This is especially true of the extensive ethnographic, linguistic, ethnohistorical, and some minor archaeological investigations carried out under the Maya research program. Taken as a body, these reports present the history of the CIW investigation of Maya civilization as well as the development of Maya archaeology as a scientific discipline.

This volume makes available once again the annual reports of the CIW Maya program, issued between 1914 and 1958, and originally published in the *Year Books* series. For historically minded readers the main contribution of these reports lies in the information presented on the development of Maya studies, from the unsystematic pursuit of adventurers, explorers, and crackpots, to the professionalization and formalization of a scientific pursuit. For the specialist in Maya archaeology and ethnography, these reports represent essential primary data not otherwise easily available.

MAYA STUDIES BEFORE THE CARNEGIE INSTITUTION OF WASHINGTON

When the CIW entered the field in 1914, the anthropological study of Mesoamerica was still at a formative stage. Although many fundamental changes in Mesoamerican research occurred during the middle and late nineteenth century, most of these contributions continued, as in earlier periods, to be textual and derived from research libraries (see later discussion on Brasseur de Bourbourg and Förstemann). Fieldwork remained of minor importance. Prior to this period, published archaeological studies were few and, almost without exception, were the work of Mexicans, such as the explorers of the Classic-period Maya site of Palenque (e.g., Guillermo Dupaix, José Antonio Alzate y Ramírez, Antonio de León y Gama, and José Fernando Ramírez). Contributions of another kind came from the great travelers, led by John L. Stephens and Frederick Catherwood, or from historians (e.g., William H. Prescott, Manuel Orozco y Berra, and Hubert H. Bancroft).

A lively debate had raged earlier between scholars who tended to promote indigenous American civilizations and others who considered the American cultures barbaric, a legacy from the anti-indigenists of the Age of Reason. From the 1840s there began in the United States, under the leadership of Lewis Cass, Albert Gallatin, and others, a revisionist and anti-Romantic movement stemming from William Robertson's important *The History of America* (1777), which held that the aboriginal Americans were incapable of ever having reached a high cultural level. Those who shared these blatantly racist views wished to apply to Mesoamerican cultures the same conclusions they had come to in their work on North American Indians.

By the 1880s the direction of Mesoamerican studies was altered significantly by a group of European and American scholars whose collective research would show that only after the careful study of all evidence could one hope to arrive at accurate conclusions without getting lost in a maze of speculation.

This is when modern archaeological science began in Mesoamerica. These studies, which continued to appear until 1910, are diverse. There are bound together intellectually by their "scientific positivism," a realism that rejects general theorizing in favor of a more empirical approach (Bernal 1980:144). These scholars spurned the blanket theorizing that had dominated the field about indigenous superiority or inferiority, whether the roots of indigenous culture lay within the American continent or outside it, and other views that passed judgment on the Spanish conquest and subsequent colonization. What was required was an objective study of facts. They tried, with the limited means at their disposal, to give fresh impetus to archaeology and, with it, ancient history and ethnology. They did not do much archaeological fieldwork, and what fieldwork they did employed techniques that had not advanced very far. Yet, even these efforts, added to their documentary research, brightened the outlook for genuine understanding.

A theme of fundamental importance to these textually based scholars was the decipherment of Maya hieroglyphic script. Little progress had been made in deciphering Maya hieroglyphs even though stelae, or sculptured stone monuments with inscriptions, had been known and identified as writing since the sixteenth-century Spanish conquest. The French abbé Charles Etienne Brasseur de Bourbourg, who discovered in the archives of Madrid parts of the Codex Madrid and Diego de Landa's *Relación de las cosas de Yucatán* (1864), was the first of the so-called armchair Mayanists. Following Brasseur de Bourbourg were Léon Louis Lucien Prunol de Rosny, Cyrus Thomas, Ernst Förstemann, J. T. Goodman, and Charles P. Bowditch, who were to make important studies in deciphering Maya glyphs over the next fifty years. Although Rosny had by 1876 deciphered the directional glyphs, working with the Madrid and Paris codices, and Cyrus Thomas demonstrated in 1882 that inscriptions were read by pairs of columns from the upper left, the most important epigrapher was Ernst Förstemann, librarian of the Elector of Saxony in Dresden. His library held the Codex Dresden, already published fifty years earlier by Edward King, Lord Kingsborough, in his massive nine-volume *Antiquities of Mexico* (1830–1848). Working with Brasseur's edition of Landa and the calendrical treatises of the Mexican Juan Pío Pérez, Förstemann (1886) succeeded in making remarkable advances in the decipherment of the glyphs. The great Mayanist J. Eric S. Thompson (1950:30) later praised Förstemann's accomplishments, noting that "[i]n 14 years this brilliant man had wrestled the secret of the Maya calendar from codex and stelae; he stands shoulders above any other student of Maya hieroglyphs." Remarkably, Förstemann

did not become interested in the Maya script until he was fifty-eight. In the twenty-six years that remained of his life, he concentrated on the Codex Dresden, extended his studies to include other codices as well as stelae, and succeeded in understanding fundamental characteristics of the calendrical system. Förstemann was able to show that the Maya had used place notation to base 20, and he also deciphered the signs for zero/completion. With these principles established, he unraveled the Venus tables in the Codex Dresden and, taking Landa's "calculation of ages" based on the katun, demonstrated the existence and structure of the Long Count.

The structure of the Maya calendar was now clear, but it had not yet been correlated with the Christian calendar to anchor it firmly in time. This final step was taken by Joseph T. Goodman, a West Coast newspaper owner who in 1897 published an important article describing the identification of the glyphic variations in the heads on Maya numerals. This work opened the way for the decipherment of the calendar in both the codices and on the stone monuments. It was, however, still necessary to correlate these dates with the European calendar to enable the two chronologies to be synchronized. The method discovered by Goodman, with a few subsequent minor modifications by J.E.S. Thompson, is the one most commonly used today. The Maya were now part of dated history and Goodman's correlation survives in its essentials in modern scholarship (Houston, Chinchilla Mazariegos, and Stuart 2001).

Quite apart from armchair Mayanists, such as Brasseur de Bourbourg, Förstemann, and Goodman, were the great field explorers of the period. The travels and field observations of John Lloyd Stephens, a special diplomatic envoy to Central America appointed by President Martin Van Buren, and Frederick Catherwood, an illustrator, inspired a diverse group of investigators, including Frenchman Désiré Charnay, who first photographed Maya ruins (Charnay 1888). Despite the value of these descriptive contributions, field archaeology in the Maya area during the last two decades of the nineteenth century was dominated by the valuable work of Alfred P. Maudslay and the photographs of Teobert Maler.

Maudslay, from a middle-class English family active in machine engineering, was educated at Cambridge (Graham 2002). He was a colonial administrator in the South Pacific when he visited Guatemala on a holiday in 1881 and first saw Quiriguá and Copán. He resigned from colonial service and continued to explore the region, documenting archaeological sites and monument inscriptions between 1883 and 1894. Equipped with paper and plaster of Paris for making molds, surveying instruments, and a large-plate cam-

era, Maudslay explored Tikal, Palenque, and Chichén Itzá after Quiriguá and Copán. One of his earliest visits was to Yaxchilán, from where he removed several sculptures to the British Museum (*Guide* 1923). The scientific result of Maudslay's work was the five magnificent oversized volumes published as the *Biología Centrali Americana* (1889–1902). Illustrations published in these works, for the first time, enabled scholars to study and compare detailed reproductions of the original inscriptions. Maudslay's skillful work remains unmatched; he elevated the study of Maya archaeology to a new level of competence. Photographs and drawings made from his casts by Annie Hunter remain primary research tools, and today his casts are often in better condition than the original monuments (Tozzer 1933:64; Bernal 1980:147). Without his work much of the progress made in the decipherment of Maya glyphs would have been impossible. His work has been, and continues to be, useful to many generations of scholars in the field of ancient Maya epigraphy and philology.

Austrian Teobert Maler later published many photographs of Maya hieroglyphic inscriptions (1901, 1903, 1908), which were taken in the Maya lowlands at the same time as Maudslay's work in the late 1880s and 1890s. Maler conducted extensive archaeological explorations along the Usumacinta River and published his results in a series of folio-sized monographs sponsored by the Peabody Museum of American Archaeology and Ethnology at Harvard University.

Elsewhere in Guatemala, German Adolph Bastian (1882) wrote about the sculptures at Santa Lucia Cotzumalhuapa in the southern highlands of Guatemala. Another German with many years' residence in Guatemala was Karl Sapper (1895). A geographer and ethnographer, Sapper classified Mayan ruins into architectural types and related those to ethnographic and linguistic areas. At the turn of the century Thomas W.F. Gann (1900) surveyed and excavated in British Honduras, and Edward H. Thompson (1897a, 1897b, 1898, 1904), the American Consul in Yucatán, dredged the Sacred Cenote at Chichén Itzá and excavated at other sites in northern Yucatán, including Labná, Loltún, and Uxmal. Nevertheless, the explorations of Maler, Bastian, Sapper, Gann, E. Thompson, and others remained superficial explorations, providing descriptions of various ruins but little of the data modern archaeologists are accustomed to collecting.

Although most research was being undertaken by individuals, some institutions were beginning to assemble teams to conduct investigations. The best known was that of the Peabody Museum, which began its archaeological monograph series in 1888 with a benefaction from Charles P. Bowditch. The first large-scale excavation of a Maya site sponsored and published

by the Peabody was excavated by Marshall H. Saville (1892) at Copán in western Honduras. Although based on innovative research and recording techniques, Saville's report, and the reports of his contemporaries, continued to be largely descriptive rather than analytical. Similarly, Alfred M. Tozzer at Tikal (1911) and Nakúm (1913), Raymond E. Merwin at Holmul (Merwin and Vaillant 1932), and Edgar Lee Hewett and Sylvanus G. Morley at Quiriguá (Hewett 1912, 1916; Morley 1913) also wrote descriptive treatments of their investigations in reports that Gordon Willey and Jeremy Sabloff (1980:62) characterize as "virtually modern in the accuracy of recording and completeness of presentation." These archaeologists, however, also attempted to derive a chronological system for their sites, based upon the excavation of buildings in relation to hieroglyphic inscriptions and Mayan calendrical dates.

By the end of the nineteenth century, the lure of the ancient Maya began to attract other explorers who were no longer merely the curious travelers of earlier times, but who approached the status of professional archaeologists. For example, G. Byron Gordon (1898b) deduced that a mound in the Ulúa Valley of western Honduras was the result of two superimposed construction episodes, a simple concept today but revolutionary in its day. Investigators in the Maya area began to sense the importance of material found in situ and the need to understand not only what an artifact is in itself, but the relationship it had to the rest of the environment. However inadequate this fieldwork may appear to us now, it was more modern than work that was then being carried out elsewhere in Mesoamerica (Bernal 1980:148).

With the published information already available, Eduard Seler, the most versatile researcher of the late nineteenth and early twentieth centuries, was able to demonstrate the essential cultural unity of Mesoamerica. He traveled widely throughout Mexico and Guatemala, gathering data and objects, and did almost no excavating; the vast bulk of his work was done at home in Berlin. For example, in a book closely linked with artifacts, *Die alten Ansiedlungen von Chaculá im Distrikt Nentón des Departements Huehuetenango der Republik Guatemala* (1901), Seler achieved an interpretation of the culture based essentially on archaeological objects (Seler 2003). He wrote masterly commentaries to Bernardino de Sahagún's Codex Florentine, the tonalamatl of Aubin, and the Borgia, Vatican B, and Fejérváry Mayer codices, which were perfectly reproduced thanks to funding provided by the Duc de Loubat. Seler went deeply into the indigenous calendar and religion, investigating not in broad outline but in the finest detail.

The majority of the early-twentieth-century studies mentioned above were produced by individuals,

but some show the start of a new way of approaching archaeology: namely, by enlisting the help of scientific bodies that produced journals or publications in series devoted more or less exclusively to the anthropological aspect. *American Anthropologist*, which has devoted many pages to Mesoamerican research, began publication in the United States in 1888, the same year the Peabody Museum began its archaeological series. Significant too were the publications of the Field Columbian Museum of Chicago, the American Antiquarian Society in Worcester, Massachusetts, and the Smithsonian Institution in Washington, D.C.

Many European publications came into existence at this time such as the *Journal of the Royal Anthropological Institute of Great Britain and Ireland* (1870), *Globus* (1861), *Zeitschrift für Ethnologie und Urgeschichte* (1869), *Petermann's Mitteilungen* (1886), *Internationales Archiv für Ethnographie* (1888), and *Journal de la Société des Américanistes de Paris* (1895). All of these journals are still being published except for *Journal de la Société des Américanistes de Paris*. They contained a wealth of seminal work by European scholars such as Erwin P. Dieseldorff, Ernst W. Förstemann, Ernest T. Hamy, Edouard de Jonghe, Walter Lehmann, Alfred P. Maudslay, Karl Sapper, and Eduard Seler. All of this publication activity signaled the beginnings of the professionalization of archaeology, which would make it possible for trained personnel to count on educational centers, institutes, and the other support networks of science (Bernal 1980:155).

The intellectual climate of late nineteenth-century Mesoamerican archaeology prior to the CIW work on the Maya project paralleled that of North America in general, but its emphasis was somewhat different. Mesoamerican archaeology was heavily influenced by the Old World, but more so by individual Europeans than by general intellectual or archaeological developments there (Willey and Sabloff 1980:57; Givens 1992a:78). Like that of the American Southwest, Mesoamerican and Mayan archaeologists were at an essentially "pre-problem" stage of development. The lack of questions to be tested in the field can be traced to archaeological training at universities of that time; there was little emphasis on constructing a well-ordered plan of investigation, let alone more profound theoretical guidance. These archaeological pioneers were still genuine functionalist archaeologists, however crude their methodology may have been. In this respect at least, they had a clear idea of where they were going. Other differences between Mesoamerican archaeology and that of the United States developed from the richness and grandeur of the remains as well as the existence of indigenous writing systems. These systems became the focus for both European and North American scholars; their eventual decipherment would one

day allow Middle Americanists to date sites more accurately, propose a means to correlate Mayan and Western chronologies, and to reconstruct the historical aspects of ancient civilizations.

Perhaps the best evaluation of the state of Mesoamerican studies at the beginning of the twentieth century was provided by German scholar Walter Lehmann (1909:2–3), who writes:

In spite of the variety of all these sources of information, in spite of the tremendous amount of documents already collected, we find so many errors prevailing, so much incertitude, such a number of prejudiced views, that we must take it as a warning to be modest and prudent in our assertions. It would be premature to attempt in the following work anything like a final answer to any of the questions discussed. It can hardly be too often repeated that the study of historic and prehistoric Mexico is still in its cradle; that it is necessary first of all to do away with a number of constant errors, and that what remains afterwards of well-ascertained fact is absolutely insufficient to give anything like a connected view of the former state of things in Mexico. Indeed, that will be impossible as long as systematic excavations are not made throughout the country. The whole land teems with antiquities. In former times archaeologists were satisfied with picking up potsherds and terra-cotta figures, without any heed as to their actual provenance. The word Mexico on a label appeared to be more than enough. It was only later on that travelers began to note down carefully the place where every object was found, and gave us by this means the possibility of classifying types according to localities. I may quote here, among others, the names of Désiré Charnay, Alphonse Pinart, Hermann Strebel, Eduard Seler, and Alfredo Chavero. Seler, for instance, has been enabled, in the course of his numerous and extensive travels, to define a number of well-marked local types, the spreading of which is not without importance for commercial history.

This call for increased methodological rigor and careful contextual study was about to be answered by the most ambitious proposal for archaeological research in the history of Americanist studies.

CARNEGIE INSTITUTION OF WASHINGTON BEGINS THE STUDY OF THE MAYA

The Carnegie Institution of Washington, a private, nonprofit organization engaged in basic research and advanced education in biology, astronomy, and earth sciences, was founded by the industrialist and phi-

lanthropist Andrew Carnegie in 1902 and incorporated by Act of Congress in 1904. Carnegie, who provided an initial endowment of \$10 million and later gave additional millions, conceived the institution's purpose as "to encourage, in the broadest and most liberal manner, investigation, research, and discovery, and the application of knowledge to the improvement of mankind." From its earliest years, the CIW has been a pioneering research organization, devoted to fields of inquiry that its trustees and staff consider among the most significant in the development of science and scholarship.

The work of the CIW has been carried on by its staff in various departments and divisions located in many geographical regions. In California are located its Mount Wilson Observatory and the physical and solar laboratories at Pasadena (1904), and the Department of Global Ecology (2002) and Department of Plant Biology (1903) near Stanford University. In Washington, D.C., are found the Geophysical Laboratory (1905) and the Department of Terrestrial Magnetism (1904). In Baltimore, near Johns Hopkins University, the CIW has established its Department of Embryology (1914). Several other research programs have been closed. The activities of the oceanographic laboratory (1904–1939) on Loggerhead Key, Tortugas, west of Key West, Florida, have been terminated, as have those in the Meridian Astrometry program (1905–1938) carried on in Albany, New York; the Desert Botanical Laboratory (1903–1929) at Tucson, Arizona; the Department of Genetics (1904–1971) in Cold Spring Harbor, New York; the Department of Marine Biology (1904–1939) at Woods Hole, Massachusetts; and the Department of Economics and Sociology (1904–1916) and the Nutrition Laboratory (1907–1946) in Boston (Lester 1941: 26).

Although the CIW is known today for its innovative research programs in the natural and physical sciences, it sponsored important anthropological studies from its founding. When the CIW began to plan for research in support of archaeology in 1902, it convened a panel of three of America's leading anthropologists—William H. Holmes, Franz Boas, and George A. Dorsey—to determine what work should be undertaken. Their report, which was published in the first *CIW Year Book*, was revealing. Although recognizing that there was important work to be done around the world, they advised the CIW to concentrate on American archaeology as well as on vanishing tribes, particularly those in the Americas. Until then, only a few studies had been done in the Americas, and the rise and fall of American civilizations remained largely unknown (Trefil and Hazen 2002:202).

The report was not implemented, however, and the institution instead supported a variety of pro-

grams, including ethnographic and linguistic research in the South Pacific (Churchill 1911a, 1911b, 1912, 1916, 1917; Finley and Churchill 1913; Ivens 1918, 1921) and among the Plains Indians of North America (Dorsey 1904a, 1904b, 1905, 1906), as well as archaeological investigations in northwestern North America adjacent to Siberia (Jochelson 1925, 1928) and in southwestern Asia (Müller 1906–1920; Pumpelly 1905, 1908; Ward 1910).

In 1912 CIW president Robert S. Woodward and the Board of Trustees appropriated funds to expand its activities in anthropology and archaeology. W.H.R. Rivers, Albert E. Jenks, and Sylvanus G. Morley were invited to submit competing plans for a large-scale program of anthropological research. These plans were issued in a remarkable volume published in 1913, *Reports Upon the Present Condition and Future Needs of the Science of Anthropology*. Rivers, a key figure in the development of British social anthropology, stressed the need for ethnographic research among fast-disappearing native peoples, and supported Oceania as the area that would best combine important theoretical problems with a significant relationship to the origins of American indigenous culture. Jenks, founder of the Department of Anthropology at the University of Minnesota, had published *The Bontoc Igorot* in 1905, a major study of the Philippines, and proposed a world clearinghouse for anthropology in the form of a research laboratory devoted to studies in ethnic heredity, environment, and amalgamation. The final report by Morley was equally ambitious but more specific in its details (see Chapter 1.1). Following a documentary and archaeological review of the history of the Maya and their civilization, he outlined the need for a twenty-five-year excavation program at a major site, presenting information on Chichén Itzá to justify its selection. He included details of labor resources, climatic problems, health, and restoration of architectural remains, together with illustrations and a selected bibliography.

Morley was well prepared for the task of implementing his ambitious Maya program. Born in Chester, Pennsylvania, in 1883, he developed an early interest in the ancient peoples of the Americas. Following his training as an engineer at the Pennsylvania Military Academy (now Widener University in Chester, Pennsylvania), he entered Harvard in 1904 and came under the influence of the distinguished scholars Frederic Ward Putnam and Alfred M. Tozzer. His first trip to Mexico in 1907 served as an introduction to a large number of the more important Maya sites, including Chichén Itzá and Uxmal. Practical experience in field surveying was gained in an apprenticeship under Edgar Lee Hewett of the School of American Archaeology (now School of American Research) in the McElmo Canyon region of southwestern Colorado and adja-

cent portions of the Four Corners region. From 1908 to 1914 he worked closely with Hewett in various capacities, making trips to the Maya archaeological sites of Uxmal, Tulúm, Quiriguá, and Yaxchilán. He gradually came to see little future in his position with Hewett, as Morley harbored an ambitious plan to excavate Chichén Itzá, a site in Yucatán that had not been investigated with any level of intensity since Tozzer's initial work in 1903. Morley realized that Hewett's School of American Archaeology and its modest budget could never afford such a grand plan.

On January 16, 1914, before the proposals had even been submitted to the review committee, Morley was informed that his plan was selected over the proposals by Rivers and Jenks, and he was appointed Research Associate in Middle American Archaeology (Brunhouse 1971:50–51; Givens 1992a:88). From the beginning, the Mexican authorities agreed in principle to the CIW investigations, and a more definite proposal concerning “a large archaeological project covering a long term of years at the ruins of Chichén Itzá” was to be prepared (Givens 1992a:89). And the final plan for the Chichén Itzá Project gained quick approval from the Mexican authorities since Mexico had just enacted severe antiquities laws barring trafficking in stolen artifacts and the CIW had no interest in funding museums to house collections. Unfortunately, Morley's plan to excavate the Maya site of Chichén Itzá was delayed by the Mexican Revolution and World War I.

Morley quickly adjusted his plans, devoting himself instead to “the preparation of a work containing descriptions and decipherments of all known Maya texts . . . as a ready and standard reference on Maya chronology.” Early in 1914 he completed *An Introduction to the Study of the Maya Hieroglyphics* (Morley 1915), a general work designed to make the subject comprehensible to the layperson (Stuart 1992:31). This landmark study is still in print (2001). When the United States entered the war against Germany in 1917, Morley served as a secret agent for the U.S. government. He continued his archaeological studies in northern Central America while collecting military intelligence until the end of the war.

Following the completion of this work, Morley concentrated his efforts largely on deciphering hieroglyphic inscriptions. The first major report from the CIW archaeological program was Morley's *The Inscriptions at Copán* (1920). In this enormous work, he provided interpretations of the calendrical matter on the monuments, even those with badly eroded inscriptions. Morley also spent time exploring areas of Central America other than Mexico, discovering and mapping Maya sites and deciphering inscriptions, until he was able to obtain permission and funding to finally begin

a major excavation of Chichén Itzá in 1923 (Trefil and Hazen 2002:205–206).

But he realized that many more ruins must lie undiscovered in the vast Petén region of northern Guatemala and he spent the next decade searching for them. Morley advertised a bounty of \$25 in gold to any chiclero (chicle tapper) who reported to him an unknown site with inscribed monuments. This unofficial program led to the discovery of Uaxactún, among other ruins (Coe 1993:127). Morley published the results of his Petén explorations in the multivolume *The Inscriptions of Petén* (1937–1938), for which he was awarded the Loubat Prize in 1943. This text established the general pattern for most Maya text treatments of the time (Stuart 1992:31). Thus, Morley gradually built a relative chronology for the Maya lowlands based on the time spans of the dates found at sites throughout the region. He was responsible for many noteworthy breakthroughs, including his pioneering work on the Supplementary Series, the string of glyphs including lunar data that follows Initial Series dates, and certain period-ending glyphs. Morley's contributions, although demanding some corrections in light of later work and discoveries of missing fragments, remain among the most productive efforts ever made in the gathering of dated Maya texts for scholars. His work of basic identification and recording of monumental hieroglyphic inscriptions has since been continued by Ian Graham at the Peabody Museum. Graham has done more than any other person since Morley to save the fragile written record of the ancient Maya from destruction by looters, harsh weather, and acid rain. Since 1975 he has published these inscriptions in a series of folio volumes titled the *Corpus of Maya Hieroglyphic Inscriptions*. The ultimate goal of the project is to document all Maya inscriptions.

In 1924 following the upheavals of the World War I, Morley resumed the task of recruiting a team of young archaeologists for a massive investigation of the ancient Maya at Chichén Itzá. Archaeological employment with the CIW was a choice assignment at a time when salaried positions in archaeology were rare. No CIW archaeologist ever had to coordinate his research with an academic schedule, for they never taught; nor did they have to spend time preparing proposals for uncertain funding, for CIW support was almost limitless. None of them had to devote time or energy to negotiating excavation permits with governments, for CIW had long-term agreements. Staff artists were available in the field and at CIW headquarters, and the archaeologists were guaranteed publication.

Few of the archaeologists Morley would recruit had advanced degrees in anthropology, including Morley himself (Black 1990b:355). The research teams at Chichén Itzá and Uaxactún included Monroe Amsden,

Frans Blom, John S. Bolles, Jean Charlot, J. O. Kilmartin, Paul S. Martin, Ann Axtell Morris, Earl H. Morris, Harry E.D. Pollock, Edith B. Ricketson, Oliver G. Ricketson, Karl Ruppert, Edwin M. Shook, A. Ledyard Smith, Robert E. Smith, Gustav Strömsvik, and George C. Vaillant. It is said that A. Ledyard Smith and Robert E. Smith were recruited for the Uaxactún dig by Oliver Ricketson at the bar of the Fly Club, one of the dining clubs at Harvard University. Harry E.D. Pollock was another Fly member. Strömsvik, who later directed the project at Copán, was a Norwegian sailor who had jumped ship in Progreso, Yucatán, and began his career at Chichén Itzá repairing CIW trucks. Edwin M. Shook started his career as a draftsman, and Tatiana Proskouriakoff as a staff artist in Washington, D.C. Several others, including Monroe Amsden, Carl E. Guthe, Samuel K. Lothrop, Earl H. Morris, Oliver G. Ricketson, George C. Vaillant, and Robert Wauchope, were former fieldworkers at Pecos Pueblo in Arizona under the supervision of Alfred V. Kidder. This core group of archaeologists would establish themselves as among the leading Mayanists for many decades.

Field research in the Maya area at the beginning of the twentieth century was considerably different and more complex than it is today. Informal accounts of fieldwork (E. Lothrop 1948; S. Lothrop 1961; Shook 1990; J.E.S. Thompson 1963; Wauchope 1965b; Willey 1988f) describe the difficulties in planning, as well as implementing, major field programs. For example, at the beginning of the century transportation was difficult. Some railroads existed and there were roads used by oxcarts for short distances outside of larger towns. Field travel, however, was usually entirely by mule or by bearers. There was a lack of reliable, or even unreliable, maps. When work began at Uaxactún in 1926, there was not even a supply of water. Everything, including workers, equipment, and provisions, had to be transported up the Belize River in small boats and on muleback for several days through the jungle. Buildings had to be constructed and crops planted for both men and mules. Shipments from New Orleans had to be planned months in advance, calculating for the needs of the camp on their scheduled date of arrival, and packaged so that they could be loaded on mules. One of the fundamental changes has been the improvement in living and health conditions. Before World War II almost all travelers in the tropics experienced multiple infections of malaria and recurrent episodes of dysentery. Cures that took months in the first half of the of the twentieth century are accomplished in days by modern medicine. John Owens, director of the second expedition of the Peabody Museum, who died of fever at Copán in 1891 and is buried in the Great Plaza at Copán, was probably the only archaeologist who died on the job. Yet, several, including Morley and Ricketson,

probably shortened their lives as a result of illnesses contracted in the field.

Excavations were carried out at Uaxactún and Chichén Itzá in the late 1920s and early 1930s. According to the thinking at the time, Maya culture, in the Classic period as it is known today, peaked at two main centers: the more ancient in the Petén lowlands, called the Old Empire, and the more recent in the Yucatán peninsula, called the New Empire. Morley did well to select to study Uaxactún and Chichén Itzá as the most representative centers of the two eras. In addition, he had already shown that Uaxactún possessed the earliest inscribed date then known, the one on the famous Stela 9 discovered by him on May 6, 1916.

THE UAXACTÚN PROJECT

Uaxactún is a moderate-sized center in the southern lowlands located just forty kilometers to the north of the much larger Tikal. Morley selected it as the first of three sites for investigation in part because in the 1920s the earliest known dated stela in the lowlands was located there and because the dated monuments indicated that this site had had a long occupation. Intensive archaeological excavations were carried out at Uaxactún for many years, first by Frans Blom in 1923, then under the direction of Oliver G. Ricketson from 1926 to 1930, and finally under A. Ledyard Smith and Robert E. Smith from 1931 to 1937. The study of Uaxactún was probably the most important archaeological project in the Maya area until the University of Pennsylvania Museum's field research at Tikal in the late 1950s and early 1960s.

In contrast to the Chichén Itzá Project with its emphasis on architectural reconstruction, the Uaxactún Project was a scientific success, giving the first full picture of the rise and fall of a Classic Maya site, which is still useful and valid today. With the publication of the major monographs describing research at the site between 1937 and 1955, archaeological knowledge about the ancient Maya, particularly the elite, expanded dramatically. The Uaxactún Project solidified general understanding of facets of elite culture that had already begun to be established (Sabloff 1990:39; 1991). In the realm of architectural surveys and excavations, research at Uaxactún and elsewhere showed a clear pattern of construction and use of space, particularly in the Classic period. The architectural reconstruction drawings by Proskouriakoff (1946) of Structure A-V and other buildings brought the sterile ruins to life. Several methodological innovations at Uaxactún have become standard in current field research. The trenching and dismantling of architecture as developed Oliver Ricketson and, later,

A. Ledyard Smith, at Uaxactún, produced a wealth of information and an intellectual legacy that continues to be felt, perhaps most strongly through its establishment of a baseline ceramic chronology (R. Smith 1955). For example, Robert Smith's testing for stratified refuse deposits remains one of the most widely applied methodologies in Maya archaeology (Black 1990b:354), as does A. Ledyard Smith's partially successful attempts to correlate dated monuments to architectural phases.

THE CHICHÉN ITZÁ PROJECT

The second important site to be explored and partly reconstructed by the CIW under Morley's direction was Chichén Itzá. Work began in 1924 and had a number of objectives that were later summarized by Alfred V. Kidder (1930b:96). He writes:

The Chichén Itzá Project has differed from most archaeological undertakings in the New World in that from its inception Dr. Morley has striven for three definite objectives over and above the usual single one of recovering specimens and information. These may be stated as follows: to conduct the work in a manner calculated to create a feeling of confidence by the Mexican government and people in the good faith of foreign scientific agencies; to handle the site in such a way as to make a permanent record of the artistic achievement of the Maya; and to develop Chichén Itzá as a focal point for correlated researches.

Kidder continues with detailed explanations of how these aims were achieved and what problems were met along the way. It is unfortunate that these ideals are not now pursued and that in Mexico some see as unacceptable even accurate reconstructions that give the public a chance to appreciate something of their country's ancient art (Bernal 1980:173–174). The Chichén Itzá Project, despite seventeen years of research, remains an archaeological enigma. Michael Coe (1993:128), a Mayanist from Yale University, has suggested that most of the archaeologists spent their time under Morley putting fallen buildings back together for the edification of tourists and very little time reconstructing a cultural picture of the ancient Maya at Chichén Itzá. Still, the CIW work at Chichén Itzá left a legacy of impressive and properly reconstructed ruins, detailed architectural descriptions, accurate reconstructions, and a large corpus of sculptured monuments, panels, and glyphic texts. Several innovative programs were initiated at Chichén Itzá. The successful negotiation of contracts between the CIW and the Mexican government were based on two unprecedented stipulations: that the CIW would return all artifacts to the country of origin after analysis and, in

the case of Chichén Itzá, it would preserve from additional damage any architectural remains that were uncovered. J. O. Kilmartin's map of the site ranks as one of the first professional maps of a Maya site. The chronological presentation by Earl Morris of the excavation and reconstruction methods used at the Temple of the Warriors between 1925 and 1928 is probably the first adequate discussion of methods from a Maya site. An experimental milpa was maintained at Chichén Itzá to investigate soil exhaustion as a major factor for the diminishing decline of yields (Morley 1947:148), and during the seventeen years the CIW carried on archaeological investigations at Chichén Itzá, a free medical clinic was maintained for the Yucatec Maya of the surrounding region (Morley 1947:31).

THE TAYASAL PROJECT

The third early Maya excavation program was conducted at Tayasal. In 1921 and 1922 Carl E. Guthe conducted excavations at Tayasal, a large island in Lake Petén Itzá in northern Guatemala, believed to have been occupied by the Itzá after leaving Chichén Itzá in northern Yucatán. The purpose of the research was to verify the historical and geographical information contained in the early reports on Tayasal (Means 1917), to secure an accurate plan and extent of the ruins, and to carry out appropriate preliminary excavations (Guthe 1921, 1922; Kilmartin 1923).

NEW DIRECTIONS FOR THE CARNEGIE MAYA PROGRAM

In the late 1920s a decision was made to expand the scope of the Maya program. In 1928 President John C. Merriam asked Alfred V. Kidder to evaluate the CIW Maya program and visit all the localities where the institution was working. At the end of the study Kidder recommended to Merriam the organizational changes needed to advance the program. The following year a decision was made to form a larger administrative structure. The CIW Board of Trustees designated the new administrative body, the Division of Historical Research, and placed Kidder in charge (Woodbury 1973:52).

Kidder's selection in 1929 as chairman was the result of several separate circumstances. Unlike Morley, Kidder had earned a doctorate in anthropology and was a professional, anthropologically oriented archaeologist. As a distinguished pioneer archaeologist in Southwestern Pueblo prehistory, Kidder had for some fifteen years worked in the American Southwest where he had developed innovative excavation techniques, particularly in the use of stratigraphy. This background was excellent preparation for Maya studies, as was the concept that archaeological work should be sup-

ported by contributions from a number of related fields. Additionally, Kidder's 1929 field season at Pecos Pueblo was to be his last making him available for new projects. The perception by the Board of Trustees indicated that a new direction was needed for the Maya program, one that involved the better coordination of field efforts. The apparent smuggling of a jade object by Thomas Gann, a close friend of Morley, was a violation of the Mexican Antiquities Law and may have influenced the removal of Morley from his leadership position (Givens 1992a:90). In any case, Morley would spend the remainder of his career with the Carnegie Institution of Washington working on Maya epigraphy.

ALFRED V. KIDDER

Alfred Kidder spent most of his early years in New England. In 1904 he entered Harvard as a premedical student but decided on archaeology as a career after spending the summer of 1907 in Arizona and Utah with Edgar Lee Hewett and Morley. He continued his fieldwork in the Southwest for the next few years and received his doctorate from Harvard in 1914 after writing a thesis on Southwestern pottery. Kidder continued his Southwest research under the Peabody Museum of Harvard University until 1915, when he was appointed director of excavations at the Pecos ruins for the Phillips Academy at Andover, Massachusetts, a position he held until 1929. His was the first systematic stratigraphic archaeological excavation in North America, as well as the largest undertaking of its kind. At Pecos, Kidder made use of the stratigraphic method on a large scale and extended it into a regional strategy of determining cultural chronology. This introduction of a systematic methodology to a field previously unsystematized led Kidder to write *An Introduction to the Study of Southwestern Archaeology* (1924), now a classic in American archaeology. This book also provided the basis for the "Pecos Classification," which was derived during the first Pecos Conference held in 1927. The classification provided a chronology of the cultures in the Southwest, starting with the early Basketmakers and extending to the Pueblo cultures of later historical times. By the late 1920s, Alfred Kidder had become involved with other archaeological interests, and he had considerable knowledge of Mesoamerica.

After Kidder became head of the Division of Historical Research at the CIW in 1929, he put into action his long-anticipated plans for investigations in Mesoamerica. Until his retirement in 1950, Kidder directed intensive and extensive excavations at archaeological sites in Mexico and Guatemala. Kidder had a clear goal for this project: he wanted to keep in mind that

the course of human history in this one particular area was but a part of the much more embracing story of man and society at large (Willey 1988a). He was looking not only at excavating but at joining these various sites in order to reconstruct the chronological range of the Maya culture and gain a new perspective as to its origins. Again this was a major undertaking for Kidder. It included a pan-scientific, or multidisciplinary, approach, and these archaeological excavations were some of the first to use teams of specialists to help analyze artifacts and human remains. Kidder opened up investigations into physical and social anthropology, ethnology, linguistics, environmental studies, geology, and geography, to name just a few. It was this conception of a broad-based approach to Maya culture history that was his most significant contribution to anthropology. CIW staff members and colleagues from other universities became involved with the Maya, living or dead, as well as with their environmental settings during these investigations. H.E.D. Pollock (1980:xxiii) describes the excitement of the time: "The 1920s were a period of great vitality in Mesoamerican archaeology, and by the end of the decade there was considerable searching for new directions in the pursuit of Maya studies."

At the close of the 1920s new developing technology was incorporated into the service of archaeology. With the help of Charles Lindbergh's flights over the Yucatán peninsula in 1929, the CIW inaugurated aerial archaeology in Mesoamerica, as well as the early stages of a coherent site-distribution analysis program. Aerial archaeology became a valuable tool in the location of new sites as well as possible transport routes between various Maya cities. Another aerial survey was conducted the following year by the University of Pennsylvania Museum.

Kidder's redirection of the division's efforts in Mesoamerica began by broadening the program to include all pertinent sciences in the study of the cultural development of the Maya (Kidder 1937). In 1928 he had already begun the task of formulating the needed changes in the division's archaeological work.

DEVELOPMENT OF THE PAN-SCIENTIFIC APPROACH

Alfred Kidder's goals for the pan-scientific approach appeared in summary form in a short paper published in 1928 in the *Bulletin of the International Committee of Historical Sciences* (1928:749–753):

1. Further study of the sequence of cultures in the Valley of Mexico, from the earliest agriculturists to the great civilizations that began early in the Christian era;
2. Reconnaissance of the Guatemala highlands, to better understand the nature of the ancient Maya

influence on or occupation of this area where so many Maya Indians were still living;

3. Intensive excavation of a large Maya site in order to trace its growth step by step and to develop techniques for reconnaissance excavation at sites too large or too remote for complete excavation; and,
4. Comprehensive investigation of the peninsula of Yucatán in cooperation with research workers of other disciplines.

Substantial progress was immediately made in advancing this research agenda. Kidder's former student, George C. Vaillant, was already at work in Mexico and, by 1931, Oliver G. Ricketson was to begin the CIW reconnaissance of the Guatemala highlands. The program directed by Morley had already begun intensive work at Uaxactún, a major "Old Empire" site. The ongoing program at Chichén Itzá was to provide a foundation for the further work in Yucatán.

In Kidder's pan-scientific approach, the archaeologist would supply the prehistoric background, the historian the documentary record of the conquest and the Colonial and the Mexican periods, and the sociologist would consider the structure of modern life. At the same time, studies would be made on the botany, zoology, and climate, and on agriculture, economic system, and health conditions of the urban and rural, European-mixed and indigenous populations. It was hoped that definite conclusions of far-reaching interest would result, that new methods for examining problems of race and culture contacts would be developed, and that an increased familiarity with aims of other disciplines would grow.

The plans were proposed to CIW archaeologists and other investigators at a conference that Kidder arranged at Chichén Itzá in January 1930, two months after his appointment to and the evolution of the Department of Historical Research into a new Division of Historical Research. Kidder promptly published a brief report on the conference in *Science* (Kidder 1930a). The archaeologists accepted Kidder's premise that historical evaluation of the archaeological knowledge derived from Morley's excavations could be made more precise by an accurate knowledge of environmental conditions, supplied by specialists in biology, geology, and other natural sciences. Data on the social condition of the Maya, past and present, would be collected by workers in documentary history, medicine, comparative linguistics, and the several social sciences (Kidder 1930a:391).

Kidder noted that knowledge gained from this multidisciplinary approach not only would benefit the individual subdisciplines, but also would gain cumulative importance, because "geographical concentration would permit pooling of data, interchange of ideas, as well as formulation of combined attack upon prob-

lems of common interest” (Kidder 1930a:391). Kidder posited that all scientists interested in the resolution of archaeological problems, in addition to accumulating knowledge in their own fields, should be in continuous communication with other investigators working on similar problems. Although the CIW ultimately did not have the funding or manpower to undertake all that was required to fulfill this vision, considerable progress was, nevertheless, achieved.

The first formal indication of Kidder’s desire to combine history and archaeology in the CIW program can be found in his first annual report for the division. He (1930a:391) wrote:

[T]he term history has been used as a symbolic of a desire to do away with the somewhat rigid distinction which has generally been drawn between archaeology and history. The work of the Section is, of course, archaeological in that it deals with material remains rather than written records. But archaeologists seek to gather from ruined buildings and potsherds the same sort of knowledge that historians derive from books and manuscripts; and while the subject matter and therefore, the primary methods of the two disciplines are naturally unlike, their ultimate aims are identical, for both archaeology and history strive to recover and to interpret the story of man’s past. Archaeology, however, has all too generally been prosecuted as if the excavation of specimens were an end in itself. Antiquities have, as a rule, been collected more for their beauty than for what they might tell of the doings and the thoughts of human beings who made them. Emphasis in archaeology is generally shifting, however, from things to what things mean; and archaeological finds are fortunately coming more and more to be considered as historical documents.

Kidder further noted that Mayan research could be likened to historical research if certain definite and logical methods were employed. In his plan, the first step was to make a record of the sequent events that characterized the career of the people under investigation. The second step was to seek causes and explain the interrelations of those events. This called for studying the previous two classes of information to formulate “those fundamental laws which have governed the past and which therefore may reasonably be expected to shape, in the future, the course of human affairs” (Kidder 1937:218).

EXPANSION OF THE MAYA PROGRAM

During his first decade with CIW, Kidder initiated or expanded a variety of research activities to supplement the more conventional archaeological work,

which continued. Kidder’s second annual report to the CIW in 1931 reflects other new directions (Chapter 1.19). This report was a landmark in Mesoamerican archaeology, a major attempt to enrich the narrow archaeological work with a broad range of anthropology and other disciplines. In the coming years Kidder repeatedly helped accelerate a shift of emphasis from objects to what they meant. The 1931 report reflects the rapidity with which important new kinds of research got underway: ongoing archaeological work at Chichén Itzá and Uaxactún is reported on by Sylvanus G. Morley, Karl Ruppert, and A. Ledyard Smith; Oliver G. Ricketson described the start of research in the Guatemala highlands; Henry B. Roberts summarizes ceramic studies aimed at continuing the pioneering work in 1927 by George C. Vaillant in his influential doctoral dissertation; Harry E.D. Pollock discusses plans for a systematic survey and analysis of ancient Maya architecture; and Sylvanus G. Morley reports on new field investigations at Yaxchilán in the Usumacinta drainage of Chiapas.

The ethnographic program of Kidder’s broad multidisciplinary approach was directed by Robert Redfield of the University of Chicago. He initiated a new examination of folk cultures, which required the development of new concepts and methods for investigation. He and several colleagues undertook a study of modern Yucatec Maya communities, ranging from the city of Mérida through the town of Chan Kom to smaller villages of the Indians of Quintana Roo. A number of young Latin Americans conducted ethnographic research, including Alfonso Villa Rojas, who became perhaps the most distinguished native researcher; Fernando Camara Barbachano (University of Puerto Rico), Calixta Guiteras Holmes (Museo Nacional de Mexico), and Ricardo Pozas Arciniegas (Universidad Nacional Autónoma de Mexico), who studied the Tzotzil and Tzeltal Maya in highland Chiapas; and Antonio Goubaud Carrera (a Guatemalan ambassador to the United States and former director of Instituto Indigenista Nacional of Guatemala), who studied the Kekchí Maya of the northern highlands.

Other new directions were documented in subsequent division annual reports by many different people, including George C. Shattuck (Department of Tropical Medicine, School of Public Health, Harvard University) on the medical survey of Yucatán; Morris Steggerda (Department of Genetics, CIW) on physical anthropology and human geography in Yucatán (to which was added later human geography); Manual J. Andrade (University of Chicago) on linguistic research among the modern Maya; F. W. Gaige (University of Michigan) on botanical and zoological studies of the Maya area; France V. Scholes (University of New Mexico) on research of the history of Yucatán; and Ralph L.

Roys (a businessman, language student, and part-time member of the CIW staff) on the translation of the Books of Chilam Balam, seventeenth-century copies of older books in the Maya language, preserving history, traditions, and ritual texts. These investigations were supplemented by additional studies, including biological studies by Cyrus L. Lundell (ethnobotany) and L. C. Stuart (herpetology); Robert Wauchope's study of modern Maya house building as an aid to understanding the house ruins associated with archaeological sites; extensive archaeological excavation and restoration at Copán, Honduras, by Gustav Strömsvik (and this led to detailed ceramic studies made later by John M. Longyear); the extension to the Maya region of Anna O. Shepard's studies of ceramic technology; analysis of modern Guatemalan textiles and weaving by Lila M. O'Neale; J. Eric S. Thompson's archaeological excavations at San José, Belize, and subsequent work at Cotzumalhuapa on the Pacific slope of Guatemala; and Morley's study of the genealogy and history of the Xiu family, traditional rulers of Uxmal, based on family papers that recorded details back to the year 1418.

In the years following 1931 a number of other projects were undertaken, mostly in collaboration with scholars at other institutions. For example, James H. Kempton and Guy N. Collins (Bureau of Plant Industry, United States Department of Agriculture) studied the past and present agricultural methods of the Maya; Rollins A. Emerson (Cornell University), Wilson Popenoe (United Fruit Company), and Raymond Stadelman conducted studies of agriculture; Arthur S. Pearse (Duke University) studied the freshwater fauna of Yucatán; R. G. Stone (Blue Hill Observatory, Harvard University) undertook climatological studies in the Maya area; Wallace W. Atwood (Clark University) and Rollin A. Atwood (University of Florida) studied the physical geography of the Guatemalan highlands; Charles W. Cooke (U.S. Geological Survey) made geological studies in Yucatán; and Sol Tax (University of Chicago) conducted ethnographic research in the highland Maya communities of Panajachel and Chichicastenango.

The first decade of Kidder's administration can be characterized as a period of increased activity within the scope of the program and of the acquisition of multidisciplinary data to better enable understanding of Maya cultural development. At the same time, during his tenure Kidder expressed concern about the general failure to study and classify material properly and to publish the results. He traced this shortcoming to a difficulty in raising publication funds, to a lack of time available to the average archaeologist, and to the casual attitude of many institutions toward the "issuance of reports as an essential and immediate sequel to field work." He advocated shorter field seasons, the

use of fewer workers, the preparation of annual publications, and the completion of up-to-date finished manuscripts at least before the start of a new field season (Wauchope 1965a:159). In 1940 a new publication series, *Notes on Middle American Archaeology and Ethnology*, began under the editorship of J. Eric S. Thompson. This series was a minor, albeit highly valuable, device for making available important information not likely to appear elsewhere. Papers included were short notes on specific specimens or topics, and when the series was ended in 1957, 131 short, but useful, papers had been published.

WORLD WAR II AND THE BEGINNING OF THE END

When the United States entered World War II in 1941, all field programs in the Maya region were temporarily closed as many of the staff left for the war or military-related activities. Although substantial writing was accomplished during the war years and important field programs were undertaken again in 1945, the decreasing support by the CIW and threat of possible termination year after year eroded the possibility of the grand synthesis that Kidder had hoped to complete. And the careers of several CIW archaeologists were interrupted by the war. Harry E.D. Pollock was a major with the photographic division of the Army Air Corps from 1941 to 1944 in North Africa and Italy. Gustav Strömsvik participated in the North Atlantic convoys in the Royal Norwegian Navy and served in the Normandy invasion. He later held an administrative position at Norwegian headquarters in Edinburgh. Lieutenants George W. Brainerd and E. Wyllys Andrews served overseas, the former in India and the latter in the Office of Strategic Services (OSS), precursor to the Central Intelligence Agency (CIA). Karl Ruppert, a volunteer in the American Field Service, drove an ambulance with the British forces in Burma and later served with the U.S. Medical Corps in Italy. In spring 1945 he was transferred to northern Europe where he assisted with the evacuation of wounded and helped to clear captured concentration camps. John H. Denison also served as an ambulance driver in North Africa. Robert E. Smith spent 1942–1944 as assistant to the U.S. military attaché in Guatemala. Edwin M. Shook was engaged in the production of quinine at the large El Porvenir plantation in Guatemala. Abraham M. Halpern was an instructor of Japanese and director of the language program in the Civil Affairs Training School at the University of Chicago. Robert S. Chamberlain was senior cultural assistant in the U.S. Embassy in Guatemala, and Francis B. Richardson served as legal attaché at the embassy in Ecuador. John H. Denison, who died of pneumonia while serving with the Fighting French Corps in North

Africa in 1943, is the only known CIW casualty of the war.

Remarkable advances had been made by the 1950s in the development of archaeology as a scientific discipline, thanks to the now-established technology of stratigraphic excavation and environmental reconstruction, which were capable of yielding considerable quantities of information. What had come into being was a fully professional archaeology, albeit one that still displayed, and continues to display, certain features from its nineteenth-century origins. Archaeologists did not seek to study each and every problem, only those that were newly emerging. These emerging problems are still worth working on, even today, and additional new ideas have extended the frontiers of possible investigation. One can now stand and gaze at Chichén Itzá, Uxmal, or Copán, because of the work done at that time and as the result of a series of underlying assumptions that continue to influence archaeology today. Even if only in broad outline, the progress of Maya civilization across time and space could be visualized for the first time, a holistic perspective on pre-Hispanic culture began to emerge, and something was now known of the origins of that culture.

After World War II's end, in addition to investigators returning from the war, the CIW program was further enhanced by the addition of several new scholars, thus continuing the broad and varied style of research that characterized the CIW of the 1930s. For example, George W. Brainerd, who revived the study of Maya ceramics in 1939 after H. B. Roberts left the program, returned and completed his monumental *The Archaeological Ceramics of the Yucatán*, published posthumously by the University of California Press in 1958. Francis B. Richardson, who studied fossil footprints in Nicaragua, was replaced by Howell Williams, a vulcanologist from the University of California. E. Wyllys Andrews IV, from 1940 onward, carried on important investigations in Yucatán, where he later excavated at Dzibilchaltún (1961, 1980) and Becán (Andrews IV, Andrews V, and Brown 1975) under the sponsorship of the Middle American Research Institute at Tulane University and National Geographic Society. Linguistic research on the Maya was continued after the death of Manuel J. Andrade by Norman McQuown, and physical anthropology studies continued through the collaboration of T. Dale Stewart of the Smithsonian Institution.

KLUCKHOHN, TAYLOR, AND CRITICISM OF THE CARNEGIE PROGRAM

Despite its accomplishments, the work of the CIW was coming under attack by the early 1940s. Although regarded as one of the leading American archaeolo-

gists of his time, Alfred Kidder also received harsh criticism for being too conservative in his research as well as for conclusions that seemed to lack significance. Clyde Kluckhohn, an assistant professor at Harvard University, who frankly acknowledged his few contributions to Maya research, published an essay titled "The conceptual structure in Middle American studies," in *The Maya and Their Neighbors* (1940), a festschrift to the great Mayanist Alfred M. Tozzer. Kluckhohn argued that the greater perspective made possible by his regional detachment justified his criticism that Maya research in general, and CIW program in particular, lacked methodological rigor. He leveled serious criticism at the entire basis and aim of the CIW Maya program, praising its fact-collecting technique but stating that its "methodological and theoretical development appears stunted indeed." He characterized its "justly praised scheme for a many-sided attack by specialists drawn from various disciplines as merely pursued with no questioning of fundamental premises and with complete acceptance of traditional assumptions and concepts, thus largely lacking relevance to the primary aims of anthropology." In his essay he (1940:42–43) states, "I should like to record an overwhelming impression that many students in [Middle American studies] are but slightly reformed antiquarians." He continues,

There seems a great deal of obsessive wallowing in detail of and for itself, . . . [D]o researches which require large funds for their support require no social justification other than that of quenching certain thirsts for knowledge on the part of a relatively small number of citizens? . . . I suspect that unless archaeologists treat their work quite firmly as part of a general attempt to understand human behavior they will, before many generations, find themselves classed with Aldous Huxley's figure who devoted his life to writing a history of the three-pronged fork. In Middle American studies up to this time I have been unable to find much evidence of awareness of or interest in the relevance of research and publication to what [Ralph] Linton has asserted to be the prime task of all anthropologists . . . to discover the limits within which men can be conditioned, and what patterns of social life seem to impose fewest strains upon the individual.

He concluded with the comments that "the very sophistication at the levels of method and technique makes the methodological and theoretical naiveté of Middle American studies stand out in shocking contrast" and that "factual richness and conceptual poverty are a poor pair of hosts at the intellectual banquet."

How much influence Kluckhohn's critique of CIW

Maya research had on the institution's directors is unknown, but it was soon reinforced by a much more extensive and carefully documented attack on the program. During the war, a student and intellectual surrogate of Kluckhohn's, Walter W. Taylor, submitted his doctoral dissertation at Harvard on the history, current methodological bases, and needed future directions of archaeology (1943). Subsequently, a revised version of it prepared under a Postwar Fellowship in the Humanities given by the Rockefeller Foundation was published as *A Study of Archaeology* in 1948. Among the six U.S. archaeologists whose work he analyzed in detail—James B. Griffin, Emil W. Haury, Alfred V. Kidder, William A. Ritchie, Frank H.H. Roberts, and William S. Webb—in order to determine their aims, stated or unstated, and their accomplishments measured against those aims, Kidder received the greatest attention.

Taylor found very little of which he could approve, mainly because of a continuing lack in Kidder's publications of syntheses presenting all aspects of the life of a prehistoric group, and also because of the repeated "failure" of publications to present fully enough the details of provenience, materials, dimensions, and associations. The CIW and its entire archaeological program were strongly criticized. Among the devices by which Taylor documented a lack of a cultural synthesis was a table analyzing the CIW publications on Maya archaeology, which showed that out of 79 major and minor works, nearly all published prior to 1946, 50 were descriptive; 21 dealt with epigraphy, calendar, and chronology; and 8 were interpretive. He thus was able to demonstrate that "anthropological" problems had been largely ignored by Kidder and his fellow workers, assuming that the "descriptive" works were essentially useless as a basis for later "anthropological" studies (Woodbury 1954:293). Many of his comments were justified by the record as it then stood, and he either was unaware of or doubted the eventual accomplishment of the future grand synthesis that Kidder looked forward to. The publication had an immediate impact and was widely hailed (Daniel 1951; Guthe 1952)—although it was condemned by some (Burgh 1950; Rouse 1953; Woodbury 1954). And it has continued to be cited as one of the most thorough analyses of the nature and accomplishments of American archaeology (Woodbury 1973:76). Taylor (1948:67) concludes his attack on Kidder with this dismissive assessment:

Kidder has provided us with some of our finest statements as to the obligations, aims, and potentialities of archaeology. But he has been saying one thing, while results have added to quite another. When Kidder writes theory he

often talks historiography and anthropology. When he directs fieldwork and publishes reports, he talks comparative chronicle.

Taylor's arguments were directed to the goal of dislodging Americanist archaeologists of the 1940s from their preoccupation with time-space systematics, and to encourage them to make more and better use of their data. He describes this shifting focus from a concern solely with chronology to a recognition that archaeology should be a means of recovering cultural contexts that are as full-bodied as possible (Watson 1983:x-xi).

A reading of the Division of Historical Research's annual reports makes it obvious that Kidder agreed thoroughly with the goals that Taylor proposed and was aware of the need for methodological rigor. Yet it is also abundantly clear that almost none of the monographs and shorter papers of the Maya program had yet reflected clearly Kidder's turn "from things to what things mean" (Woodbury 1973:75). Much of the archaeological field staff consisted of men devoted to fieldwork, and few of them had substantial training in anthropology and even those certainly were not social scientists in the sense called for by Kluckhohn (Woodbury 1973:75). Even Kidder's recognition of the need for directing archaeology to the large goal of "understanding" man in all of his complexity, and the "laws" that may govern the growth and decline of civilizations, was tempered by his constant insistence that the time for synthesis was mainly in the future and the present need was for facts.

Yet, criticism by Kluckhohn and Taylor did not go unheeded and may be seen in the CIW's subsequent Mayapán Project (Pollock, R. Roys, Proskouriakoff, and A. Smith 1962) and Gordon R. Willey's Belize Valley Project (Willey, Bullard, Glass, and Gifford 1965). The methodological emphasis on detailed mapping, intensive survey, and excavation of a variety of structural types, including a large number of presumed residential structures, can be seen as a response to Taylor.

In the 1946 annual report Kidder announced the need for a general review of the Maya program, including "the problem of whether or not it will be best to continue intensive research on preconquest Maya." He obviously was aware of the CIW administration's doubts about the value of the CIW archaeological program in comparison to other programs; however, no general review of past work or fundamentally new program for future work was published.

VANNEVAR BUSH AND THE END OF THE CARNEGIE INSTITUTE OF WASHINGTON MAYA PROGRAM

The second decade of Kidder's administration at the CIW had focused on the problem of reduced fund-

ing caused by the reallocation to the hard sciences as the result of the impending conflict of World War II. The dissolution of the CIW work in Mesoamerica had been a slow but steady process. Vannevar Bush, John C. Merriam's replacement as president of CIW in 1937, was a distinguished physicist. He had served as dean of the School of Engineering at the Massachusetts Institute of Technology. As President Franklin D. Roosevelt's top science advisor during World War II, Bush had been chairman of the President's National Defense Research Committee (1940), Director of the Office of Scientific Research and Development (1941–1947), and Chairman of the National Advisory Committee for Aeronautics (1939–1941). He had organized and coordinated the science effort for World War II from CIW's headquarters building in Washington, D.C. Bush had overseen more than 200 defense-related ventures, including the development of nuclear fission and the Manhattan Project. Under his direction, CIW scientists had become heavily involved in war work, ranging from the development of antibiotics and the proximity fuse to testing machine-gun barrels. Bush's idea of federally funding science led to the creation of the National Science Foundation in 1950. Not surprisingly, Bush was also no supporter of the humanities.

The antiquarian foundations of Mayanist studies also had been working against the general perception of the CIW program as a scientific one. A colleague of Kidder's, Richard Woodbury (1973:71) has suggested that the failure of the archaeology program to win a permanent place in the CIW was the result of a mindset that archaeology was seen as chiefly "the pursuit of adventurous young men of good family and private income." More likely, the CIW's interest in social sciences and humanities had been declining and its leader—as noted above—had seen the approach of World War II as justification for greater emphasis on the so-called hard sciences and their technological hardware. Such a reorientation seems to have been controversial among some members of the CIW Board of Trustees. Col. Charles Lindbergh, appointed to the Board of Trustees in 1934, resigned from the board at the annual meeting in January 1941, because the CIW was concentrating its research efforts on developing war materials to aid the government.

Just before Bush began his plan to shut down CIW operations in Mesoamerica, Kidder proposed several potential projects. One unsuccessful proposal asked the CIW to underwrite the cost of developing the use of radiocarbon dating for archaeology. Kidder then proposed undertaking a large, longitudinal project at Tikal, as well as a program of research that would turn attention from the Maya to relationships between the two major centers of civilization in the New World, Mesoamerica and the Andes (Givens 1992a:115). These

were not accepted by the CIW although excavations at Tikal were soon initiated by the University of Pennsylvania Museum with Edwin M. Shook, and later William R. Coe, as field director. The Tikal proposal was partially carried out in the 1950s by the Institute for Andean Research's Program on the Interrelationship of New World Cultures. Kidder was, however, able to negotiate a final CIW field project in the Maya region: Mayapán.

MAYAPÁN PROJECT

A decision was finally made for the limited continuation of research at a single site in Yucatán. In 1948 Kidder (*Year Book* 47:207) wrote that "the general outline of the Maya's career had been obtained [and that] indefinite continuance along the lines formerly pursued might lead to over concentration on detail and narrowing of outlook." He announced the need for a "quantitative reduction in objectives and a shift from a general study of the Maya past to an attack upon some specific phase thereof . . . promising to yield, within a predictable time, results of both historical and methodological importance." Consequently, the work in Guatemala and the Petén was closed down, and by the time Kidder retired from the CIW in 1950, the Late Postclassic-period site of Mayapán in northern Yucatán was selected for extensive historical and archaeological investigation under the direction of Harry E.D. Pollock. This research would examine the final expression of pre-Hispanic Maya culture.

This final major CIW archaeological project, conducted between 1949 and 1955, was the first attempt at an extensive field investigation and typological and functional analysis of domestic structures, the first attempt to excavate a sample of the entire range of structural types at a single Maya site, and the first systematic attempt to view a single Maya site within a regional framework. In addition, functional analyses were conducted on the larger civic and religious structures, and there was extensive use of the direct historical approach made possible by the historical researches of Ralph L. Roys. Anticipating modern trends in graduate-student training, Mayapán included the first training program in the Maya region to actively employ groups of graduate students from multiple universities. Some of these was Robert M. Adams (Ph.D., Chicago, 1956), Robert H. Barlow (Universidad Nacional Autónoma de México), Heinrich Berlin (Universidad Nacional Autónoma de México), William R. Bullard (Ph.D., Harvard, 1960), Ann Chowning (Ph.D., Pennsylvania, 1958), David DeHarport (Ph.D., Harvard, 1960), Joseph A. Hester (Ph.D., University of California, Los Angeles, 1954), William N. Irving (Ph.D., Wisconsin, 1964), William T. Sanders (Ph.D., Harvard,

1957), Donald E. Thompson (Ph.D., Harvard, 1955), and Raymond H. Thompson (Ph.D., Harvard, 1955). Despite these and other innovations and advances in research methodology, the emphasis of the project generally remained within the still-dominant traditional approach. Noticeably, the project focused on the elite aspects of the site and, although excavators did try to sample all domestic structures, grander buildings received most of the attention.

THE CARNEGIE INSTITUTION OF WASHINGTON MAYA PROGRAM CLOSES

In 1958 the CIW abolished its Division of Historical Research and thus ended a program of research begun more than forty years earlier by Sylvanus Morley and that had produced more than 300 publications from the CIW outlet alone. The closing was announced unceremoniously in a brief notice in the English journal *Man: Journal of the Royal Anthropological Institute of Great Britain and Ireland*, in which its accomplishments were summarized by Pollock (1958:435–449; Chapter 1.47) in his final report as director. The official director's and others' correspondence, financial documents, reports, news clippings, and miscellaneous items remain at the headquarters of the Carnegie Institution of Washington (Appendix 1). The extensive archaeological archive was turned over to the Peabody Museum of Archaeology and Ethnology at Harvard University (Appendix 2). The ethnographic and linguistic notes of Robert Redfield, Sol Tax, Manuel Andrade, Norman McQuown, and others was deposited at the University of Chicago Library and eventually made available on microfilm (Appendix 3), and the enormous historical archive compiled by France V. Scholes for his history of the Yucatán Project was eventually deposited at the Latin American Library at Tulane University (Appendix 4).

The momentum of institutional research that characterized the golden years at CIW was—as CIW's projects lost steam—embraced and carried on by other institutions. Many developed major projects in the Maya area, including the University of Pennsylvania Museum's Tikal Project, the Peabody Museum's Belize River Valley Project, Tulane University's Dzibilchaltún Project, and Mexico's National Institute of Anthropology and History's second major program at Palenque.

Morley came the closest of any CIW archaeologist to presenting a synthesis of the entire research program in his popular and successful *The Ancient Maya* (published in 1946 and now in its sixth edition). Although the need for a comprehensive review of the work of the CIW was mentioned in the 1938 *Year Book* by Kidder, only a four-page summary of projects in the Maya field, covering twenty-five years of work,

was presented. In his final report Kidder (1950:192; Chapter 1.39) merely wrote of the work of the past two decades:

The program of Maya research inaugurated with the establishment of the Division in 1929 was a very ambitious one. It could not be carried through as originally planned in the hopeful days before the Depression and the war. There is not space here to review its objectives, to summarize its results, or to consider the reasons for its successes and failures. This will be done in a forthcoming report.

The “forthcoming” report was never written. It was premature to hope for a synthesis in 1939 or 1940 of the first ten years of the expanded program of Maya research, as many of the components were term investigations not yet completed, and some were included in a boldly experimental way that in the end contributed rather little. According to Woodbury (1973:80), this was not a fault of the program but instead an inevitable risk in any pioneering research.

The CIW efforts toward full publication of the work, however, are reflected not only in the numerous major reports issued as publications of the CIW, but also in the many monographs published by cooperative arrangements elsewhere (Andrade and Máas Collí 1990–1991; Bolles 1976; Brainerd 1958; Cámara Barbachano 1966; Chamberlain 1951; Guiteras Holmes 1992; Hansen and Bastarrachea Manzano 1984; Hester 1954; Kidder, Jennings, and Shook 1977; O'Neale 1965; Pollock 1980; Popol Vuh 1950; Proskouriakoff 1963; Redfield 1950; Redfield and Villa Rojas 1962; Roys 1965, 1972, 1973; Rubinstein 2002; Scholes and Menéndez 1936–1938; Scholes and Roys 1966, 1968; Solís Acala and Roys 1949; Tax 1953, 1963, 1964; R. H. Thompson 1958; Tovilla 1960; Villa Rojas 1990; Wauchope 1948, 1975).

ASSESSMENT OF THE CARNEGIE INSTITUTION OF WASHINGTON MAYA PROGRAM

As we have seen, the CIW Maya program was attacked for not taking a broader view of the cultural context and for focusing primarily on description. Nevertheless, the program made some real and significant contributions. The CIW Maya program laid a broad foundation for subsequent research, while turning immediate interests from narrowly defined epigraphic and archaeological goals to broader anthropological aims. The approach to the study of the ancient and modern Maya was, of course, still loose and experimental in its structure, without the more precisely defined problems and

specific goals that we are accustomed to today in interdisciplinary research. Expectations were unreasonably high, however, especially when one considers that a final synthesis was expected by Kidder at the end of the second decade of his directorship. More recent large-scale multidisciplinary archaeological efforts at Tikal, Copán, and elsewhere have been far from reaching final syntheses in ten or twenty years.

Moreover, the CIW Maya program played a critical role in the development of Maya archaeology in ways that range from field methods to chronology, to the emerging concepts of the origin and development of Maya civilization. The CIW efforts in southern Mesoamerica were gradually expanded from essentially an epigraphic study to intensive excavations at Uaxactún and Chichén Itzá and into other areas of research, including ethnographic, linguistic, physical anthropological, ethnohistorical, and environmental. Kidder's pan-scientific approach to archaeological problems was presented during the Chichén Itzá Conference of January 1930 and resulted in an expansion of archaeological interpretation. Kidder recognized that archaeologists must consult with other specialists in order to resolve archaeological problems more effectively and to enhance data interpretation. This multidisciplinary emphasis has become the model for longitudinal research projects in Mesoamerica.

Therefore, it seems only fair when evaluating the results of the CIW Maya program to recognize its many individual successes and its role in providing a basis for current studies of the Maya, rather than to fault it for failing to fully achieve its broad and general goals. Not the least of its accomplishments was the remarkably full publication of results so that data from the work in the 1930s and onward are easily accessible to scholars today. Richard Woodbury (1973:80) has noted that with the termination of the CIW's Division of Historical Research, Maya research lost one of its organizational mainsprings, as well as a primary publication vehicle. Although the CIW had been taken to task by Kluckhohn (1940) and Taylor (1948) for a tendency to neglect interpretation in favor of data, its contribution was still enormous and included the publication of many key works, ranging from Morley's compendiums of site-specific calendrical text analysis (1920, 1937–1938) to J.E.S. Thompson's summary of Maya writing (1950). These publications, whether descriptive or analytical, have provided a foundation for all modern archaeological research in the Maya region (Appendix 6).

Morley, perhaps more than any Mesoamerican archaeologist since, created exceptional goodwill between archaeologists and their national hosts. Contract negotiations in Mexico, Guatemala, British Honduras, and Honduras were based on two unprecedented

stipulations: that the CIW would return all antiquities to the country of origin after analysis and, in the case of Chichén Itzá, that the CIW would preserve architectural remains. The Chichén Itzá Project (1924–1937) left a legacy of properly reconstructed ruins, detailed architectural descriptions, solidly based artistic reconstructions, and a large corpus of sculptured monuments, panels, and glyphic texts. CIW work at Copán (1935–1941) was a joint project cosponsored by the government of Honduras, the first time a local government actually helped fund major archaeological excavations at a Maya site, providing labor and transportation of supplies and personnel within Honduras. The 1933–1934 work at Quiriguá continued a policy of helping host countries restore the major Maya ruins and, in the 1940s, the United Fruit Company appointed Kidder as adviser for its reconstruction project at Zaculeu in the western highlands of Guatemala. Stanley H. Boggs, John M. Dimick, and Gustav Strömsvik, former CIW archaeologists, were assigned to the project.

Morley, in particular, had an unusual talent for popularizing the story of the Maya and conveying the excitement of discovery to the public through clear, informative text and attractive photographs and illustrations. Morley's *The Ancient Maya* (1946), published in numerous editions (1947; Morley and Brainerd 1956; Morley, Brainerd, and Sharer 1983; Sharer 1994), is a triumph in popularization and is found in most libraries and bookshops today. Morley, Ann Axtell Morris (1931), Earl Morris (1931), and J. Eric S. Thompson (1954) also wrote stimulating accounts for the general public in popular books and magazines such as *National Geographic*.

Morley, Kidder, and Pollock administered one of the largest and most complex archaeological research organizations ever (Table 1). Their task was to coordinate efforts by CIW staff and related Middle American government interests in order to resolve relevant archaeological and anthropological problems. Kidder, in particular, excelled in the organization of large-scale archaeological research and was successful in soliciting additional funds from CIW. It is a rough measure of Kidder's success as an administrator that between 1929 and 1936, the CIW appropriations for archaeology more than doubled (Trefil and Hazen 2002:209). Indeed, the budget of the program increased from \$3,000 in 1914–1915, to begin a survey of archaeological sites in the Petén, to \$31,000 in 1924, when excavations began at Uaxactún and Chichén Itzá, to \$150,000 during the Depression. Between 1913 and 1940, the budget for historical research, including archaeology, totaled \$2,700,000, or approximately 6 percent of expenditures by the Carnegie Institution of Washington. The average annual expenditure of the

historical research program was approximately \$100,000 (Lester 1941:28), still considerably more than most archaeological projects today. The organizational arrangement of the CIW program would be replicated in subsequent projects at Tikal, Kaminaljuyú, Copán, and elsewhere.

At the beginning of the CIW program there was no systematic method for recording excavation or architectural plans, sections, or elevations, and no formal training in archaeological techniques existed. Most field methods were transferred from working in the American Southwest. Perhaps the greatest change in Mesoamerican archaeology has resulted from its growth, both in diversification of interests and in number of practitioners. Early archaeologists often lacked a formal academic background or had transferred from another discipline. Today, albeit under the umbrella of anthropology, archaeological specialists are trained at major research universities. Another radical change in archaeology has come from the development of techniques to determine absolute age, specifically radiocarbon dating. Kilmartin's map of Chichén Itzá is one of the first professional maps of a Maya site (Morris, Charlot, and Morris 1931:plate 2), and his annual report (Chapter 1.12)] provides the first substantial published account of the difficulties of mapping lowland Maya sites. Subsequent mapping projects at Uaxactún, Mayapán, Kaminaljuyú, Copán, and other sites continue to use Kilmartin's mapping procedures and cartographic conventions.

Despite its failure to meet the standards of the theoretical forerunners of the "New Archaeology," CIW was considerably ahead of its time in a number of areas that helped make archaeology a professional, scientific, and internationally cooperative pursuit. The CIW formulated high standards of scholarly research for its archaeological program; refused to remove artifacts for museum collections; and, as part of its excavation program, pledged to faithfully restore ancient structures so that the public could enjoy them as part of the national heritage.

Stratigraphic analysis is now a common feature throughout the Maya area, mainly as a result of the work of the CIW program. At the beginning of the twentieth century, archaeological data collected were few, geographically spotty, and imprecise. Method and theory were nonexistent. Only the spectacular received attention and data regarding typology and chronology were generally lacking. The first Maya ceramic stratigraphy was identified by Raymond Merwin during his 1910–1911 excavations at Holmul in Guatemala, but not published until after his death (Merwin and Vaillant 1932). In 1924, stratigraphy was identified and examined at Uaxactún by Oliver Ricketson and George Vaillant, and at Chichén Itzá by Vaillant.

Rather than focusing exclusively on finds, CIW publications also addressed methodological concerns associated with problems posed by Maya sites. A major effort by A. Ledyard Smith in 1929 at Uaxactún to relate the stelae to plaza floors and adjacent temples by trenching represents the first substantial and nonstructural excavation undertaken in the Maya lowlands (Black 1990b:95). Under Ricketson (1926–1930), excavations focused on the E-Group at Uaxactún revealed the first substantial evidence of a Preclassic occupation in the Maya lowlands. Morris's chronological presentation of the excavation and reconstruction methods of the Temple of the Warriors is perhaps the first adequate discussion of method in a Maya site report (Morris, Charlot, and Morris 1931, 1:91–164).

The value of pottery and its analysis in establishing antiquity and for determining the geographic range of given cultures and subcultures at various periods also was established at CIW excavations at Uaxactún. The ceramic report for Uaxactún by Robert E. Smith (1955) produced a wealth of information and an intellectual legacy that continues to be felt, perhaps most strongly through its establishment of a baseline ceramic chronology. The report also established an unequaled standard of description and illustration.

The first concerted effort to obtain residential settlement data in the southern Maya lowlands was possibly the most important work of the 1929 season at Uaxactún. Enrique Shufeldt, under A. Ledyard Smith's supervision, mapped a cruciform-shaped area surrounding the site center "to determine the number, frequency, locality, and possible relations to each other, of house mounds and chultuns, for the purpose of estimating populations" (Ricketson 1929, 28:317).

Perhaps one of the most experimental and holistic innovations of the CIW program was its emphasis on ethnographic analogy in interpreting archaeological remains by striving to link prehistoric sites or cultures with living Maya. This approach is perhaps best exemplified by J. Eric S. Thompson's work at San José in Belize. An experimental milpa was established at Chichén Itzá to consider soil exhaustion as a major factor for the diminishing decline of yield, complementing Raymond Stadler's (1940) extensive research on milpa agriculture in northwestern Guatemala in 1936 and 1937. Robert Wauchop's excavation of modest architectural structures at Uaxactún and his surveys of modern Maya domestic construction in 1934 and 1935 provided baseline data for Maya settlement archaeology.

Similarly, the study of the historical demography and subsistence strategies of the Maya was formalized during archaeological, ethnographic, and ethnohistorical research throughout the Yucatán peninsula. The CIW research in the Yucatán peninsula investigated modern Maya production of maize and

the assumed reliance by ancient Maya populations on similar subsistence techniques and products, and it used caloric needs and settlement characteristics of modern Yucatán populations to predict maximum possible densities.

The use of documentary evidence to bridge the present and past was incorporated into archaeological field research at the end of the program. The pioneering work of Ralph L. Roys, France V. Scholes, and Robert S. Chamberlain laid the foundation for subsequent ethnohistorical and historical research in the Maya region. The archive pertaining to the Colonial-period Maya, assembled by Scholes and presently at the Latin American Library at Tulane University, serves as a rich resource for ethnohistorians.

Perhaps most innovative of all at the time of its inception was the establishment of a free medical clinic maintained for the Yucatec Maya of the surrounding region. Basic medical care and medicines were distributed among them for free during the seventeen years that the CIW carried on archaeological investigations at Chichén Itzá. The medical survey, organized and directed by the Department of Tropical Medicine of the Harvard School of Public Health, was carried out in 1932 under the auspices of the CIW as part of the institution's broad purpose to make use of many disciplines in its continuing study of the Spanish-Maya civilization. This "action anthropology" or "public interest anthropology" is increasingly popular in current research programs. Both the free medical clinic and the medical survey of the CIW Maya program were seminal in the development of modern action anthropology as well as medical anthropology. Thus, despite some inevitable shortcomings, the achievements and accomplishments of the CIW Maya program were indeed significant.

ORGANIZATION OF THE VOLUME

This volume includes the publication of annual reports pertaining to the Maya research program published in the *CIW Year Books* from 1914 through 1958, as well as Sylvanus Morley's initial proposal of research that was the catalyst for the entire program (Chapter 1.1). The content of the original reports has been rearranged from a temporal to a thematic and regional organization. For example, all administrative reports by the director now appear together. Similarly, all reports pertaining to Chichén Itzá appear in one place and are arranged in sequential order. The thematic sections, ordered by chapter, include the following categories:

1. Administrative
2. Art and Architecture

3. Environment
4. Ceramics
5. Textiles
6. Hieroglyphic Writing
7. Linguistics
8. Ethnography
9. Ethnohistory
10. Physical Anthropology

Regional sections, arranged by country, state (in the case of Mexico), and specific archaeological site, include the following categories:

11. Belize
12. Baking Pot
13. Pusilhá
14. San José
15. Campeche (Mexico)
16. Calakmul
17. Edzná
18. Chiapas
19. Bonampak
20. Yaxchilán
21. El Salvador
22. Guatemala
23. Kaminaljuyú
24. Sites Near Lake Petén (Polol, Chakantún, Tayasal, Topoxté)
25. La Muralla
26. Piedras Negras
27. Quiriguá
28. Uaxactún
29. Zacualpa
30. Honduras
31. Copán
32. Nicaragua
33. Quintana Roo
34. Cobá
35. Tabasco and Veracruz
36. Yucatán
37. Chacchob
38. Chichén Itzá
39. Ek Balam
40. Mayapán
41. Uxmal
42. Yaxuná

All of the reports are published as they appeared originally with only a few exceptions. We have left out a few unnecessary photographs, corrected obvious typographical errors, and modernized some place names, but we did not change the content. Dated spellings, misspellings, grammatical errors, and awkwardness have all been allowed to stand. Deletions, of which there are some, are indicated by the use of ellipses. Notes are presented where explanation or clarification may be helpful to the reader. Words are explained in the glossary if they cannot be found in the standard abridged dictionaries of English and Spanish. Notes in the originals have been, wherever appropriate, incorporated

into the text. Bibliographic citations have similarly been placed within the text rather than as endnotes.

As presented, the reports published in the *CIW Year Books* from 1914 through 1958 document the development of the CIW program and also the transition of Maya studies from an informal and amateur pursuit to a formalized professional endeavor. Although most of the material contained herein was eventually incorporated into published monographs, there are notable exceptions, such as the ceramic research of Henry B. Roberts. Similarly, the largely unpublished extensive linguistic work of Manuel J. Andrade and his successor, Norman A. McQuown has only been

available in microfilm format (see Appendix 4). The ethnographic work of Robert Redfield has appeared in several monographs, but much of Sol Tax's work at Chichicastenango in the Guatemala highlands was never published. Similarly Asael Hansen's urban anthropological research at Mérida was not published for many decades (Hansen and Bastarrachea Manzano 1984). The ethnohistorical work of Frances Scholes, Ralph Roys, and Robert Chamberlain was partially published and the archives of their primary sources photographed at the Archivo General de Indias in Seville remains an immense treasure at Tulane University's Latin American Library in New Orleans.

TABLES

ARCHAEOLOGICAL RESEARCH AT THE RUINS OF CHICHÉN ITZÁ

INTRODUCTION

THE GREEKS OF THE NEW WORLD

This question is often asked: What aboriginal people of the New World had achieved the highest culture before the coming of Europeans? And indeed it is a matter of recognized importance to determine which Native American race had traveled farthest on the road from savagery to civilization.

A comprehensive review of man and his achievements in the Western Hemisphere discloses but two peoples whose claims need be considered for this distinction, namely, the Inca¹ of Peru and the Maya of southern Mexico and Central America. These two nations were the leaders of civilization in their respective continents, and in each case their nearest competitors were far behind. But when it comes to a choice between the two, to awarding pre-eminence to one over the other, justifiable differences of opinion exist. In the first place, neither race surpassed the other in every branch of human activity. In some fields the Inca excelled, and in others the Maya. The Inca were preceded by several earlier civilizations, to which they were

largely indebted for essential features of their culture, whilst the Maya had no such inheritance. They were originators and not adapters of art and architecture. Maya remains present an unbroken cultural development extending over 1,500 years. It is admitted that the Inca surpassed the Maya in the textile arts and possibly also in governmental and social organization. But even granting this partial superiority, the writer believes that a broader comparison of the two cultures will award first place to the Maya. It is certain that the latter far excelled the Inca in the arts of sculpture, painting, and architecture, and in the sciences of writing, arithmetic, astronomy, and chronology. Their history recorded in their hieroglyphic inscriptions covers a range of more than a thousand years; their observations in astronomy reveal a knowledge of the movements of heavenly bodies equaled by that of few peoples of antiquity; their system of chronology kept an account of elapsed time which in accuracy rivals our own; while in sculpture, painting, and architecture the Maya have been most aptly termed "The Greeks of the New World."²

THE AREA COVERED BY THE MAYA CIVILIZATION

The region occupied by the Maya was the low Atlantic coastal plain in what are now the northern parts of Honduras and Guatemala, and of British Honduras, and the Gulf States of southern Mexico, an area approximately 500 miles [805 km] north and south by 300 miles [483 km] east and west.

The southern part of this region is abundantly watered by a network of streams, which have their rise in the Cordillera, while the northern part, comprising the peninsula of Yucatán, is entirely lacking in such water courses and were it not for large natural wells found here and there it would be uninhabitable.³ In the south the country is densely forested, though occasional savannas break the monotony of the tropical jungles. The surface is rolling and is traversed in places by ranges of hills, which in British Honduras rise to a maximum elevation of 3,700 feet [1,120 m] above the sea level.⁴ In the north the nature of the soil and the scarcity of water are not favorable to the growth of luxuriant vegetation, and this region is therefore covered with a smaller forest growth and a sparser bush than the area to the south. The deer, monkey, tapir, peccary, jaguar, and numerous other mammals are abundant throughout the entire region and doubtless formed a large part of the food supply in ancient times. The climate is tropical. There are two seasons, the rainy and the dry, the former corresponding roughly to our summer and autumn, and the latter to our winter and spring. At present there are over 20 different tribes,

representing more than a million people, who speak dialects of the Maya language. It might be added in this connection that in spite of the loss of their former glory the Maya still remain the finest aboriginal people of North America.

THE ANCIENT MAYA

The ancient Maya probably emerged from savagery about 2,000 years ago, at least their earliest dated monuments can not assuredly be referred to a more remote period, and any estimate as to how much time before that had been required to develop their complex calendar and hieroglyphic system to the point of graphic record is only conjectural. One thing alone is certain: a long interval must have elapsed from the first crude and unrelated scratches of savagery to the elaborate and highly involved hieroglyphics found on the earliest monuments.

By the end of the second century AD, the Maya had emerged from savagery and were at the threshold of civilization. There then began an extraordinary development throughout the southern part of the area. City after city sprang into prominence, each contributing by its growth to the general uplift. During this period all of the great southern cities flourished: Tikal, Copán, Palenque, Naranjo, Piedras Negras, Yaxchilán, Quiriguá, and Seibal.⁵ Besides being the largest, the first three mentioned were also the leaders in cultural progress. The period during which these cities flourished lasted for upwards of 400 years, or until the close of the sixth century AD. It has been called "The Golden Age of the Maya," since, in so far as sculpture is concerned, it is best comparable with the classic period of Greek art.

The causes which led to the decline of civilization in the south are unknown. It has been suggested that the Maya were driven from the various cities above mentioned by barbarian pressure from the south, east, and west; or again, that the Maya civilization, having run its natural course, collapsed through sheer lack of physical ability to go forward, or, in other words, through racial decay and deterioration. It matters little what explanation is advanced to account for the general decline, this one all important fact remain: Just after the close of Cycle nine of Maya chronology, or about 600 AD, there is a sudden and final cessation of dates in all the southern cities. Some universal calamity apparently overtook the Maya people at the opening of their Tenth Cycle, as a result of which their homes were abandoned and their country left desolate.

About a century before the end of Cycle 9, however, the country lying to the north, that is, the peninsula of Yucatán, seems to have been discovered and colonized for the first time. Some have even gone so far

as to ascribe the downfall of the southern cities to this very event; and it does not seem improbable that, after the discovery of Yucatán by the Maya and the subsequent opening of that vast region to colonization, the southern cities commenced to decline. As the new country waxed in strength and power the old waned, so that by the end of the sixth century AD the rise of the one and the fall of the other had been accomplished.

The occupancy of Yucatán marked the dawn of a new era for the Maya, although their Renaissance did not begin at once. At first the struggle for bare existence must have largely absorbed the energies of all, and not until their foothold was secure could there have been much time or wealth available for the cultivation of the aesthetic arts. Then, too, at first there seems to have been a feeling of unrest in the new land, a shifting of houses and testing of new localities, all of which retarded the development of sculpture, architecture, and other arts. Bakhalal, the first settlement in the north, was abandoned after an occupancy of only 60 years. Chichén Itzá, destined to become the greatest of all Maya cities, was the next settlement, and although occupied for more than a century, it also was abandoned and the search for a new home resumed. One group of Maya, moving westward from Chichén Itzá across Yucatán, occupied the city of Chakanputún, in the western part of the peninsula, about the beginning of the eighth century. Here they are said to have lived for about 200 years or until 960 AD, when this city was destroyed by fire. By this time, however, the Maya had become familiar with their new environment and their energies once more had begun to find outlet in artistic expression. The Transitional Period was at an end, and the Maya Renaissance was under way.

The opening of the eleventh century witnessed important and far reaching political changes in Yucatán. After the destruction of Chakanputún, the horizon of Maya activity expanded. Some of the Maya returned to their former homes at Chichén Itzá and reoccupied that city, while others established themselves at a new site called Mayapán. At this time also the city of Uxmal was founded. In 1000 AD these three cities formed a confederacy, under the terms of which each shared equally in the government of the country. Under the peaceful conditions which followed this coalition, the arts blossomed anew. This was the second and last great Maya epoch. During its course there doubtless arose, the many cities whose crumbling ruins are to be found today throughout the length and breadth of Yucatán. When these were occupied, the country must have been one vast hive of activity, for only large numbers of people, actuated by a great religious and aesthetic awakening, could have left remains so extensive.

This era of universal peace was abruptly terminated about 1200 AD by an event which shook the political structure to its foundations and disrupted the "Triple Alliance," under whose beneficent rule the land had grown so prosperous. The ruler of Chichén Itzá seems to have plotted against his colleague of Mayapán, and in the disastrous war which followed, the latter (by the aid of Nahua allies brought from Mexico) utterly routed his opponent and drove him from his capital.

The conquest of Chichén Itzá seems to have been followed during the thirteenth century by attempted reprisals on the part of the Itzá, which plunged the country into civil war. After the dissolution of the "Triple Alliance" it seems probable that Chichén Itzá was given by the ruler of Mayapán to his Nahua allies in recognition of their assistance. At least many of the buildings at Chichén Itzá are strongly Nahua in character, a condition which prevails at no other large city in the Maya area.⁶

According to the early Spanish chroniclers, the fourteenth century was characterized by increasing arrogance and oppression on the part of the rulers of Mayapán, who found it necessary to surround themselves with Nahua fighting men to keep in check the rising discontent of their subjects. This unrest culminated about the middle of the fifteenth century, when the Maya nobility, goaded to desperation by this oppression, banded themselves together under the Lord of Uxmal, sacked Mayapán, and slew its ruler.

The destruction of Mayapán sounded the death knell of the Maya civilization. As the native chroniclers tersely put it, "(After this) the chiefs of the country lost their power," and again, "They were destroyed and it was ended with those called Mayas." The population was split into a number of warring factions. Ancient feuds and jealousies, no longer held in leash by a strongly centralized government, were doubtless revived, and again the land was rent with strife. Presently, to the horrors of civil war were added those of famine and pestilence, each of which visited the peninsula in turn, carrying off great numbers of people.

These several calamities, however, were but fore-runners of worse soon to come. In 1517 Francisco de Cordova landed the first Spanish expedition on the coast of Yucatán,⁷ and, although he was repulsed after having accomplished little more than the discovery of the country, this was the beginning of the end. The following year Juan de Grijalva descended on the peninsula, but meeting with such determined resistance, he also sailed away, having gained nothing. The next year (1510) Hernán Cortés landed on the northeastern coast, but re-embarked for Mexico after a few days' stay. Seven years later, in 1526, Francisco Montejo obtained the title of "*Adelantado* of Yucatán" from the

King of Spain and set about the conquest of the country in earnest. He landed an expedition of 500 men on the northeastern coast and, with the elaborate formalities customary to such occasions, took possession of the country in the name of Charles V. This empty ceremony proved to be only the prelude to a sanguinary struggle which broke out almost immediately thereafter and continued with extraordinary ferocity the Maya fighting desperately in defense of their homes. Indeed it was not until 14 years later, or on June 11, 1541 (old style), that the Spaniards, having defeated a coalition of Maya chieftains near the city of *Icheansihoo* (Mérida), effected the permanent occupancy of the country.

Here ends the independent history of the Maya. For 15 centuries this remarkable people had preserved their cultural life singularly intact and free from alien influences, only to succumb in the end to causes working from within. Through racial decay and internecine strife, the product or perhaps the price of its development, the Maya civilization came at length to naught. And while the Spanish conquest was the immediate cause which shattered this once great culture, the seeds of its decay and downfall had been sown long before the discovery of America.

PREVIOUS WORK IN THE MAYA FIELD

The archaeological importance of the Maya field was first made known by John L. Stephens, who visited the Central American republics in 1839 and 1840, on a special mission from the United States government. His charming book entitled *Incidents of Travel in Central America, Chiapas and Yucatán* [1841] still remains, after the lapse of 75 years, a standard authority on the subject; and, indeed, so far as the purposes of general description are concerned, this book and its sequel, *Incidents of Travel in Yucatán* [1843], have never been superseded.

Following the preliminary work of Stephens, there was a hiatus of nearly 50 years before a real scientific study of this region was undertaken. In the decade 1881–91, Mr. A. P. Maudslay visited the principal ruin groups previously mentioned, and, through an arrangement with the editors of the *Biologia Centrali Americana* [1889–1902], published a superb set of photographs, maps, plans, and drawings of monuments and buildings at these sites. This work is of such a high character that it easily ranks as the greatest single contribution to the study of Maya archaeology. It consists of four volumes of text and some 400 plates. Mr. Maudslay's work, however, was largely of a preliminary character. He did little excavating, but devoted the greater part of his time to surveying and mapping the sites visited, and photographing and making molds of various sculptures. The wealth of material

for the study of Maya sculpture, architecture, and hieroglyphic writing, which his work made accessible, gave a tremendous stimulus to Maya archaeology and awakened an interest which is still maintained.

In 1888 the Peabody Museum of Harvard University entered the Maya field. The first work undertaken by this institution was the exploration of the ruins of Labná in northern Yucatán; this was continued in the two years following and several other sites in the vicinity were explored.

In 1891 a more ambitious project was inaugurated, namely, the excavation of the large ruined city of Copán, in the western part of Honduras. This work was carried on for four years, and during its course much valuable material was obtained. Unfortunately, its discontinuation became necessary in 1895, bringing to a close the most important research ever made in the Maya area and, with one exception, the only intensive study of a large representative site (Gordon 1896, 1898b, 1902) that has yet been undertaken.

After the discontinuance of the Copán project, the Peabody Museum returned to exploratory work. In 1896 and 1897 the valley of the Ulúa River was visited and important collections of pottery were made (Gordon 1898a). In 1899 Mr. Teobert Maler, of Mérida, Yucatán, was sent to the Department of Petén, northern Guatemala, where for the next five years he made extensive explorations, which, however, were largely preliminary in character. Mr. Maler made sketch maps of the different sites visited, prepared plans and cross-sections of the principal buildings, and photographed all the sculptured remains he could locate. The results of his studies have been published by the Peabody Museum (Maler 1901, 1903, 1908, 1910, 1911). His chief contribution to the science has been his admirable photographs, which constitute a treasury of hitherto unknown material for the study of Maya art and hieroglyphic writing. In 1910 the Peabody Museum resumed its operations in northern Guatemala (Tozzer 1911) by sending an expedition to this region. A survey and a map of the large ruined city of Tikal were made, and several other sites in the vicinity were explored. This reconnaissance was continued in 1911 and 1912, and resulted in the discovery of several ruin groups of secondary importance.

To the Field Museum of Natural History in Chicago is due credit for the standard handbook on Maya architecture. Under the auspices of this institution, Mr. W. H. Holmes visited the principal northern ruin groups in 1894 and published the results of his observations in *Archaeological Studies among the Ancient Cities of Mexico* [1895–97]. The clear architectural sketches and restorations, and the panoramic views of the different sites described, make this publication the best scientific handbook on Maya architecture that has yet appeared.

Since 1904 the Archaeological Institute of America has maintained a Fellow in this field, and considerable data on archaeology, ethnology, and linguistics have resulted from this activity (Tozzer 1907). In 1909 the School of American Archaeology, a branch of the same institution, began the investigation of the ruins of Quiriguá, Guatemala, with the cooperation of the St. Louis Society of the Institute and the United Fruit Company. Work has been conducted for three years and will be continued until an exhaustive study of this site has been made (Morley 1912, 1913).

The University of Berlin has sent out exploring and collecting expeditions from time to time, which have resulted in the acquisition of much new archaeological and ethnological material. These expeditions have devoted themselves chiefly to reconnaissance work, little or nothing in the way of close study at particular sites having been attempted.

In addition to the field work above described, considerable research has been carried on at some of the larger universities and scientific institutions. Here should be included the pioneer work of Dr. D. G. Brinton, of the University of Pennsylvania, in the field of Maya history and mythology (Brinton 1882a-b, 1885, 1890); the masterly studies of the illuminated manuscripts by Prof. Ernst Förstemann, of the Royal Library at Dresden (Förstemann 1906), and Dr. Cyrus Thomas, of the Bureau of American Ethnology (1882); and the definitive researches in the hieroglyphic writing and Maya chronology by Mr. J. T. Goodman, of Alameda, California (1897), and Mr. C. P. Bowditch, of Boston (Bowditch 1901a-c, 1903b, 1904, 1906, 1909, 1910). These scholars have laid the broad foundations of archaeological research in Central America, and it is on their work that succeeding generations of students must build.

Maya art has been studied by Dr. H. J. Spinden, of the American Museum of Natural History, whose researches have established the chronological sequence of Maya sculpture beyond all doubt (Spinden 1913). The work of Mr. Juan Martínez, of Mérida, Yucatán, on post-Conquest Maya documents (Martínez 1910, 1912), also is entitled to special mention. Mr. Martínez is easily the foremost authority on the Maya language and his studies have shed much light on the subject of Maya mythology. The contributions of Mr. Thomas E. Gates, of Point Loma, California, on Maya manuscripts, are also worthy of notice (Gates 1910). The writer's own researches have been concerned chiefly with Maya history, chronology, and hieroglyphic writing (Morley 1910a-b, 1911a-c, 1912).

PRESENT NEEDS OF THE MAYA FIELD

From the preceding section it is clear that by far the greater part of the archaeological work hitherto con-

ducted in the Maya field has been of a preliminary nature. The work of most of the expeditions mentioned has been exploratory in character, and few of them have undertaken an intensive study of particular problems. Useful as this exploratory work has been in establishing the boundaries of the Maya civilization and in ascertaining its more obvious features, such as the number, size, and distribution of its different centers, the character of its art and architecture, the nature of its hieroglyphic writing, etc., the time has now come for a more detailed study of these problems for research rather than reconnaissance.

Maya archaeology has passed through its preliminary stages. It is now generally conceded, by those most competent to judge, that in the future the greatest contributions to the science will come from the intensive study of representative sites. Such study necessarily involves the vigorous and continued prosecution of archaeological work at some important site for a number of years. So large and complex are these ancient Maya cities that the problems they present can be solved only by an expedition operating over a considerable period.

The project contemplates the conduct of archaeological research at one of the largest centers of the Maya civilization, and the intensive study for a number of years of the site chosen. After the work has been thoroughly organized and has proceeded to the point of producing noteworthy results (perhaps a matter of several years), its scope should be gradually extended to cover the surrounding region through subordinate expeditions emanating from the original base of operation. This extension of the research is suggested simply to indicate the magnitude of the problem awaiting investigation in any special archaeological province of the Maya culture area. These problems are not so large as to be incapable of definite solution within a reasonable period of time, but yet extensive enough to engage the energies of a fairly large expedition for at least a score of years.

In selecting a site for the concentration of such research, there are several general qualifications which the place chosen should possess, namely: 1. It should be large enough and of sufficient importance to offer material for study for at least 20 years; 2. It should be the center or metropolis of the surrounding region; 3. Its archaeological significance should be such as to justify intensive investigation; and 4. It should be as healthful and at the same time as accessible as possible.

On these last two factors very largely depends the efficiency of any scientific, expedition operating in the tropics. The site which combines the greatest number of these factors is therefore the one at which extended research can be carried on most advantageously.

ADVANTAGES OF CHICHÉN ITZÁ AS A BASE OF OPERATIONS

After a careful comparison of the largest Maya cities, the writer has concluded that there are many important reasons, practical as well as scientific, why Chichén Itzá, in northern Yucatán, is better fitted for immediate intensive investigation than any other Maya center. Before giving these reasons in detail, a word as to the situation of the site may not be out of place.

The ruins of Chichén Itzá are in the northeastern part of the peninsula of Yucatán, 15 miles [24.1 km] from the nearest railroad and 100 miles [161 km] from Mérida, the capital of the state. The surrounding country is a vast limestone plain, level as a table top and destitute of water sources.

This ancient city was named after the tribe which founded it, and from the two great natural wells (or cenotes) found there: *chi*, mouths; *chen*, wells; and *Itzá*, the name of the people which settled there, hence Chichén Itzá: "The mouths of the wells of the Itzá." To these two large natural reservoirs, the city may be said to owe the fact of its existence. As the Maya moved northward into Yucatán from their former haunts, the more arid character of the new land must have troubled them greatly, hence where water was found in abundance, as at Chichén Itzá, inevitably a large city would rise. However, only one of these wells seems to have been used as a source of water supply in ancient times. This cenote is 100 feet [30.5 m] in diameter and about 70 feet [21 m] in depth to the surface of the water. Down one of its vertical sides there winds a steep stairway which terminates in a platform, where formerly the water carriers were wont to fill their jars. The remaining well, the Cenote of Sacrifice, had a more exalted use, which will be explained in another place.

We will now present in more detail the reasons why Chichén Itzá is the most promising and, at the same time, the best adapted site in the Maya field for intensive study.

SCIENTIFIC REASONS

1. CHICHÉN ITZÁ, THE POLITICAL CENTER OF YUCATÁN.

Chichén Itzá was the largest city of the Maya civilization and, as such, offers a practically inexhaustible field for research. Its temples and palaces cover an area a mile square [2.6 sq km], and surrounding this on every side, for a distance of 5 miles [8.1 km], the bush is filled with groups of outlying buildings. In addition to being the largest city, Chichén Itzá for many centuries was the political and governmental center of Yucatán, and consequently every activity, such as sculpture, mural painting, and architecture, experienced a correspondingly high development there.

2. CHICHÉN ITZÁ, THE RELIGIOUS CENTER OF YUCATÁN.

As a holy or sacred city, Chichén Itzá was pre-eminent. In the native manuscripts of the sixteenth and seventeenth centuries its inhabitants are referred to as "The Itzá, holy men" (Brinton 1882b:101, 125, 145), apparently indicating a widespread belief in the sacred character of the city and its people. This holiness was considerably enhanced by "The Cenote of Sacrifice," to which pilgrimages were made from distant points, even outside the Maya area, until the Spanish conquest in the sixteenth century. Offerings of all kinds were cast into this cenote, even including human sacrifices in times of drought, to appease the anger of the offended rain deities (Appendix 1.4). Says an early chronicler, in speaking of "The Cenote of Sacrifice":

From the court in front of these theatres⁸ there goes a beautiful and broad causeway to a well about two stone throws distant. In this well they used to have, and still have, the custom of casting living men in sacrifice to the gods in times of drought, and they hold that these do not die, even though they are seen no more. They also cast into this well many other things, stones of value and whatever else they regard as precious. And so if this country had had gold in it, it would be found in this well, so great is the devotion of the Indians to it (Landa 1864:344-346).

Recent archaeological investigations substantiate the sacred character of this cenote and the fact that human victims were thrown into it.

The causeway above mentioned commences at the edge of the broad terrace in front of the Castillo the principal temple at Chichén Itzá, and leads to a small shrine at the brink of "The Cenote of Sacrifice." From this latter point the victims were hurled into the water below. The fact that Chichén Itzá was the holiest city of the Maya, in short, "The Mecca of the Maya World," considerably increases its archaeological importance.

3. CHICHÉN ITZÁ, THE FOREMOST CITY OF THE MAYA RENAISSANCE.⁹

When the Maya moved northward into Yucatán from the older centers of their civilization, Chichén Itzá was the first large city founded in the new land. For this reason it is the best place at which to study the changes effected in the old civilization by the new environment. Under the pressure of these new surroundings, many of the customs and practices of former times fell into disuse, and finally were forgotten altogether. But side by side with this process of decay, there went on a corresponding process of growth. New needs gave rise to new ideas, and these in turn so

leavened society that in due time the Maya civilization experienced its renaissance. Chichén Itzá was the leader in this cultural revival, and it is probable that this site will furnish the best data on the various stages of its development.

4. CHICHÉN ITZÁ, THE KEY TO THE CORRELATION OF MAYA AND CHRISTIAN CHRONOLOGY.

Chichén Itzá is the only site in the Maya area that is known to have had dates recorded in both the old and the new system of Maya chronology. After the colonization of Yucatán, the system of chronology prevalent in the south, the so-called Initial Series,¹⁰ seems to have fallen into disuse. Indeed, Chichén Itzá is the only large site in the north at which it has been found. A drawing of the lintel with this remarkable inscription is given in the accompanying figure. The date here recorded was the day 10.2.9.1.9, 9 Muluc 7 Zac of Maya chronology, or approximately 600 AD. This date was found inscribed on the lintel of the principal doorway of a small and apparently insignificant temple. In place of the method of recording dates by Initial Series, there was developed in Yucatán a more abbreviated method, called the *u kahlay katunob*,¹¹ which, though less accurate, was more easily recorded. This latter method, because of its greater simplicity, prevailed until the coming of the Spaniards; and, what is of more importance, it has been accurately correlated with Christian chronology by means of several historical events, dated in terms of both the Maya and the Christian calendars. Since the whole question of the age of the Maya ruins depends upon the proper alignment and correlation of the Initial Series with the *u kahlay katunob*, it follows that Chichén Itzá is the only site at which this important question can be studied. In a word, it is the key site for the study of Maya chronology.

5. CHICHÉN ITZÁ, THE CONNECTING LINK BETWEEN THE MAYA AND NAHUA CIVILIZATIONS.

In studying any ancient civilization it is important to establish its cultural affinities; that is, to trace not only its influence upon surrounding cultures, but also the influence of surrounding cultures upon it. Chichén Itzá is the only large Maya city that ever came under strong foreign influence. It has been explained that after the defeat of the Itzá, about 1200 AD, their city was probably given over to the Nahua allies of the victorious ruler of Mayapán. Here, then, are sufficient historical grounds to account for the presence of a strong Nahua influence at Chichén Itzá. This influence is to be seen most clearly in the so-called Ball Court group. The Ball Court proper is composed of two massive stone walls, each 272 feet [83 m] long, 34

feet [10.4 m] thick, and 27 feet [8.2 m] high. These walls are parallel and 119 feet [36.3 m] apart. A small temple faces each of the open ends, and a very beautiful temple, "The Temple of the Jaguars," surmounts the eastern wall at its southern end. The name of this temple is derived from a frieze of stalking jaguars, which forms a conspicuous element of the façade decoration. An admirable restoration of this temple [is provided] by Maudslay. A comparison of this with the photograph of the building will show that it is correct, even to the smallest sculptural details. High on the side of each wall of the Ball Court, midway between the ends, there is a large stone ring fastened vertically to the face of the wall. The game played in this court was not unlike the modern game of basketball, except that in the Maya game the ball was driven through an opening at right angles to, instead of parallel with, the ground (Appendix 1.5). The Ball Court is a purely Nahua importation. The game was originated and developed in the Nahua area, whence it spread to Yucatán at a comparatively late date, probably after 1200 AD, as we have seen. Indeed there is only one other certain occurrence of a Ball Court in Yucatán, namely, at Uxmal. There are many other features of the architecture and sculpture at Chichén Itzá that bespeak Nahua origin, and few of them are found at any other Maya site (Spinden 1913:205). This condition, coupled with the historical event which probably gave rise to it, makes Chichén Itzá the site par excellence at which to study the cultural affinities between the Maya and the Nahua, the two greatest aboriginal civilizations of North America.

6. CHICHÉN ITZÁ, THE MOST LIKELY SITE AT WHICH TO FIND A MAYA "ROSETTA STONE."

The point just mentioned has an important corollary, in that the meanings of a large number of the Nahua hieroglyphs, particularly those denoting personal and place names, are known. In the lower chamber of the Temple of the Jaguars there is sculptured a band of warriors, to each of which is attached a hieroglyph drawn in Nahua style. The finding of Maya equivalents of these glyphs would shed much light on the whole question of the undeciphered parts of the Maya hieroglyphic texts. Should there then exist such a thing as a Maya "Rosetta Stone," that is, a bilingual text in Maya and Nahua, Chichén Itzá is by far the most likely place to find it.

7. CHICHÉN ITZÁ, THE MOST NOTABLE HISTORIC SITE IN THE MAYA CULTURE AREA.

Chichén Itzá has a recorded history extending over a period of 11 centuries, or from 430 AD to 1540 AD

(Morley 1910b, 1911a), This is true of no other Maya city, and indeed of no other aboriginal site in the Western Hemisphere. Recorded history pertaining to pre-Columbian centers of population is exceedingly rare; in fact, this lack constitutes one of the greatest obstacles to the study of American archaeology. In Egyptian, Babylonian, Greek, and Roman archaeology, history acts as a constant check against speculation. Therefore, when there are definite historical references to a New World site, its archaeological importance can not be overestimated.

In summing up the scientific reasons for the selection of Chichén Itzá as a base of operations for extended research in the Maya field, it may be said that this site offers far more material for the study of Maya archaeology in its various phases than any other center of the civilization.

PRACTICAL REASONS

1. ACCESSIBILITY.

Few Maya sites are so accessible from the United States as Chichén Itzá. This group of ruins may be reached from New York City, via the New York and Cuba Mail S. S. Co. (that is, the Ward Line) to Progreso, Yucatán (7 days), and the United Railways of Yucatán, Progreso to Dzitas, and wagon to the ruins (one day); or from New Orleans, via the Montes Line to Progreso (3 days), and Progreso to Dzitas and the ruins (one day). Excepting Uxmal (also in Yucatán) and Quiriguá (Guatemala), the same accessibility can not be claimed for any other large Maya ruin. Indeed, most of the others are very difficult to reach. Palenque, Tikal, Naranjo, Yaxchilán, Piedras Negras, and, Seibal, for example, are hidden in the jungles of southern Mexico and northern Guatemala, many days distant from the nearest railroads or steamship lines, and they can be reached only by very difficult travel over foot trails, often blocked by luxuriant vegetation. The accessibility of the site recommended for the base of operations has a direct bearing not only on the cost of placing an expedition in the field, but also of maintaining it there. A scientific expedition can, be sent to Chichén Itzá and there maintained more economically than at any other large center of the Maya civilization, with the possible exceptions of Uxmal and Quiriguá, above noted.

2. LENGTH OF THE FIELD SEASON.

Northern Yucatán has a shorter rainy season than any other part of the Maya area, and this fact directly influences the length of the field season at Chichén Itzá. It was the experience of the Peabody Museum at

Copán (Honduras) and of the School of American Archaeology at Quiriguá (Guatemala) that excavation could not profitably be carried on during the rainy season. The writer was in immediate charge of the excavations at Quiriguá in 1912, and he well remembers how torrential were the first rains of the season, early in May, and how suddenly they put an end to the work by flooding the diggings. The rainy season at Chichén Itzá commences about the close of May and extends until about the middle of December, leaving at least 5 months during which it is possible to conduct archaeological work without hindrance. At the southern Maya sites, such as Palenque, Tikal, Copán, and Quiriguá, the dry season is much shorter. At Quiriguá, for example, only the months of February, March, and April are entirely free from rain, and similar conditions prevail at the other southern cities. The field season at Chichén Itzá and Uxmal is almost twice as long as at any of the southern sites.

3. HEALTHFULNESS.

Chichén Itzá is by far the most healthful site in the Maya area. It is free from the malarial fevers which render Copán, Quiriguá, and Uxmal so perilous. These fevers are so pernicious at Uxmal that it is said no child born at the hacienda has ever lived to adult age (Holmes 1895-97:80). The untimely death of Dr. J. G. Owens,¹² of the Peabody Museum, at Copán in 1893, still lingers in memory as a tragic reminder of the unhealthfulness of that locality. During the three seasons the School of American Archaeology carried on work at Quiriguá, every member of the field staff suffered severe attacks of malaria at one time or another. Such conditions are of course inevitable where the rainfall is so excessive and where there is so much standing water in which mosquitoes may propagate. Chichén Itzá, with its ideal natural drainage, offers a marked contrast to the above. Mosquitoes are practically unknown there, and with this element of danger absent there is nothing to make the place unhealthful. Since the amount of work which may be accomplished by any scientific expedition depends largely on the health of its field force, the incontestable claims of Chichén Itzá in this respect should not be overlooked.

4. LABOR CONDITIONS.

The success of any large field research depends not a little upon local labor conditions, and in selecting a site for intensive study this fact should be borne in mind. In the south, two American industrial organizations have established themselves during the last decade, and these have materially increased the cost of labor in certain parts of the Maya area: the United

Fruit Company, with plantations in eastern Guatemala, Honduras, and British Honduras, and the American Chicle Company in northern Guatemala, southern Yucatán, and British Honduras. The increasing number of laborers necessary to the activities of these two corporations has steadily raised the price of labor in the regions where they operate. In 1912 the School of American Archaeology was obliged to pay 75 cents (gold) a day for laborers at Quiriguá, with every indication that the price would soon advance to one dollar a day. Indeed, the Guatemala Northern Railroad was already paying the latter price for Carib labor.¹³ Another drawback at some of the large southern cities is their remoteness from settlements of any kind, necessitating the importation of outside labor, always a costly and usually an unsatisfactory proceeding. At Chichén Itzá efficient Indian laborers may be had at from 37.5 cents to 50 cents (gold) a day. These wages are doubtless as low as those prevailing elsewhere in the Maya area, and they are from a third to a half lower than are paid in Guatemala and British Honduras by the two corporations above mentioned. The Maya Indian is intelligent, strong, and willing, and the amount of work he can accomplish in a day is astonishing.¹⁴ A working force of 50 to 75 could easily be brought together at Chichén Itzá, and for efficiency would equal, if not surpass, a similar force from any other part of the Maya area.

5. FIELD QUARTERS.

Chichén Itzá is peculiarly fitted for conducting an extended research in another important respect. There is no other ruin at which an expedition can be so intensively and at the same time so comfortably quartered as at Chichén Itzá. Indeed all the other large sites, except Uxmal, Quiriguá, and Copán, are in a tropical wilderness where it would be necessary to build more or less expensive mosquito-proof field quarters and even these three groups of ruins have no such facilities as those offered at Chichén Itzá. The question of suitable field quarters may seem relatively unimportant, but in inaugurating a work, to extend over a score of years, the comfort of the field corps becomes an item of considerable moment.

In summing up the practical reasons for conducting archaeological research at Chichén Itzá, in preference to every other Maya site, the question resolves itself into one of maximum efficiency at minimum cost. More work can be accomplished at Chichén Itzá for a given amount of money than at any other site. Measured by such a standard, only three large Maya sites, Chichén Itzá, Uxmal, and Quiriguá, are sufficiently near railroad points to be worked at low cost. While cost of operation should not weigh too heavily in se-

lecting a site for intensive study, still a reasonable return of results for the amount expended should be expected. Of the three ruins mentioned, Chichén Itzá has by far the most in its favor, and the writer firmly believes that more can be accomplished there than anywhere else in the Maya field, regardless of the amount of the annual appropriation.

NATURE OF THE PROJECT HEREIN PRESENTED

The project herein submitted to the Carnegie Institution of Washington contemplates an exhaustive study of the ruins of Chichén Itzá. This study would depend largely on excavation, but photography, mapping, drawing, and molding should be utilized as well. The ruins at Chichén Itzá divide naturally into different groups of more or less closely related structures, each group constituting a well defined unit of work (Appendix 1.3). Such are the Ball Court Group, the Monjas Group, the Group of the Columns, etc.

It is recommended to excavate this ancient city, group by group, until it is completely uncovered and the relations of its component parts are disclosed. This method has another obvious advantage: By dividing the whole research into a number of units, it will be possible to issue fairly complete reports covering finished units every 4 or 5 years. Such reports would constitute a progressive commentary on the progress of the research. It is confidently expected that important contributions to the study of Maya architecture, sculpture, painting, ceramics, chronology, and hieroglyphic writing will result from these excavations. Indeed, it is practically certain that the knowledge of these subjects will be greatly extended as the work of excavation advances.¹⁵

Accompanying the work of excavation, a reasonable amount of repair and restoration should be done. The time has passed when a scientific expedition can rifle a site of its specimens and then retire, leaving weakened buildings to fall under the destructive action of the elements. Today the best practice in archaeological work demands that walls weakened by excavation shall be permanently repaired, and that any really important site must be left in as good condition after excavation as it was found to be before. This obligation is always binding in any tropical environment, but particularly so when the site excavated is one of the largest and most magnificent cities of aboriginal America. At Chichén Itzá, moreover, the need of repair work is especially urgent. Scarcely a rainy season passes that some elaborately sculptured façade, loosened by the roots of clinging vegetation, does not fall. The whole front of the Castillo, the chief temple at Chichén Itzá, is a case in point. The wooden lintels of

the main doorway are gradually giving way under the tremendous weight of the superimposed masonry, and unless repairs are speedily made this beautiful example of Maya temple architecture will suffer irreparably. Examples of this kind might be multiplied indefinitely, but the one given above is sufficient to show the need for a reasonable amount of repair work in connection with the excavation of Chichén Itzá.

It is recommended to carry out at Chichén Itzá a research similar to that of the Smithsonian Institution in connection with the prehistoric remains in our Southwestern States. At Casa Grande, Arizona, and in the Mesa Verde National Park, Colorado, remarkable and praiseworthy work has been done under the direction of Dr. J. Walter Fewkes and of Mr. J. L. Nusbaum. Views of the Spruce Tree House, one of the cliff dwellings of the Mesa Verde National Park before excavation and after excavation clearly indicate the great improvement which a reasonable amount of repair work makes in the appearance of archaeological remains. The only previous attempt of this kind in the Maya field has been the work of the School of American Archaeology at Quiriguá, Guatemala. Here, in connection with the excavation of the principal building, the walls were relaid in cement and finished with a cement cap to render them impervious to the excessive rainfall of the region (Hewett 1911a-b; Morley 1912, 1913).

In addition to the work of excavation and repair, extensive use should be made of photography. Chichén Itzá offers a particularly rich field for the camera and this phase of the work should receive special attention. It is recommended to make a complete photographic record of the site, showing the progress of the excavations, and other features also: groups of buildings, single buildings, architectural and sculptural details, statuary, hieroglyphic inscriptions, mural paintings, etc. If an archaeological expedition is sent to Chichén Itzá, its photographic equipment should be of the best, since no branch of the work except excavation will be of greater importance.

The making of maps from accurate surveys is a necessary feature of such research. A map of the entire city, with detailed ground plans of its individual structures, is a vital part of the general plan of work and will not only shed much light on the question of the assemblage of Maya structures, but also on the much larger question of Maya social organization. The map of Chichén Itzá, although accurate so far as it goes, does not begin to cover the limits of the city, nor even to show all of the buildings, pyramids, platforms, and causeways in the area surveyed.

Molds should be made of the different sculptures recovered, including the statuary, façade decorations, hieroglyphic inscriptions, and the like. The Mexican Government takes the stand that original objects

should not be taken out of the country, and the justice of this position cannot be questioned.

After more than a century of robbery and exploitation, both Greece and Italy found it necessary to forbid by law the removal of antiquities from their domains. Mexico, with antiquities relatively as priceless as the Elgin marbles of the Old World, has an equal right of protection against similar exploitation at the hands of unscrupulous collectors. The archaeologist of today has no more in common with the pot hunter of 40 years ago than modern medical practice has to do with the quackery of the Middle Ages. In the modern science of archaeology any specimen is of value only for the story it tells of the people who produced it; and so long as the specimens found are preserved for the use of future students it is immaterial where they are housed.

This question of the ultimate disposition of objects found during the course of excavation has been the rock upon which many an archaeological expedition has foundered, not only in Mexico but also in other parts of the world. The stand herein taken, that archaeological objects belong to the country in which they are found, rather than to the finders thereof, it is confidently expected, will enlist the active interest and sympathy of the Mexican Government in this particular project. The antiquities at Chichén Itzá, whether they be in the form of statuary, reliefs, wood carvings, vases, metal ornaments, or what not, were the product of a Mexican civilization, and for that reason, originals should in all justice remain in the custody of the Mexican nation. For exhibition in museums and for scientific instruction, casts would serve as well.

Concerning the length of time which will be required to complete the work herein outlined, something has already been said. It was suggested that research in the Maya field should not be organized for a period of less than 20 years. The writer has reached this conclusion only after a careful study of the situation. The experience of the Peabody Museum of Harvard University at Copán, Honduras, and of the School of American Archaeology at Quiriguá, Guatemala, was such as to indicate that at least 5 years are necessary to complete satisfactorily a single unit of work; and it is only in the aggregate that completed units of work yield reliable scientific data. In observational sciences, final proof of any point rests on the accumulation of sufficient evidence touching thereon upon corroborative material from a number of sources, hence the desirability of continuing this research long enough to obtain such corroborative data. As stated above, the writer believes this would require a period of not less than 20 years.¹⁶ The problems presented are numerous, and a number of years of sustained effort will be required for their ultimate solution. Moreover, in making this estimate, the number of laborers em-

played in the excavations, as well as the length of the annual field season, are all important factors. The above estimate of time is based on an annual field season of 5 months, and on a working force of 50 laborers.

In conclusion the writer believes that, as a result of the work outlined, it will be possible not only to treat this particular site monographically, but also to establish the larger part of the truth concerning the whole Maya civilization.

CONCLUSION

It is the writer's belief that no other archaeological field in the New World offers such rich promise as the region occupied by the ancient Maya, and, at the same time, no equally important field has been so inadequately studied. An attempt has been made to show briefly in the preceding pages that the Maya were the most highly civilized aboriginal people in the two Americas; that their recorded history covered a range exceeding a thousand years before the Spanish conquest; and, finally, that, notwithstanding its archaeological importance, this civilization has been the subject of very little intensive study. The few exceptions noted, especially the work of Mr. A. P. Maudslay and the Peabody Museum of Harvard University, are the more conspicuous because they stand alone. It is generally recognized that the most pressing need of Maya archaeology is intensive research at some representative site through a period of years. The site best fitted for such research is, in the writer's opinion, the great ruin group of Chichén Itzá in northern Yucatán. The various reasons, practical as well as scientific, which have led him to this conclusion, have been set forth at some length, and they constitute, it is believed, a strong argument for selecting Chichén Itzá in preference to any other Maya site. The character this investigation should assume, together with its ultimate scope, has been described in detail with a brief word respecting the nature of the results which may reasonably be expected. Finally, the period of time that would be required to produce results worthy of the endeavors of the Carnegie Institution of Washington has been judged to be about 20 years.

APPENDIX 1.1

LIST OF BOOKS ON THE MAYA CIVILIZATION

Arnold and Frost 1909; Bancroft 1875-76; Bowditch 1901a-c, 1903a-b, 1904; 1906, 1909, 1910; Breton 1906; Brinton 1882a-d, 1885, 1890, 1894; Catherwood 1844; Casares 1905; Förstemann 1906; Gann 1897-98; Gates 1910; Goodman 1897; Gordon 1896, 1898a-b, 1902; Hewett 1911a-b; Holmes 1895-97; Landa 1864; Maler

1901, 1903, 1908, 1910, 1911; Martínez 1910, 1912; A. C. Maudslay and Maudslay 1899; A. P. Maudslay 1889-1902; Morley 1909, 1910a-b, 1911a-d, 1912, 1913, 1914; Río 1822; Schellhas 1904; Seler 1908; Spinden 1913; Stephens 1841, 1843; Thomas 1882, 1894-95, 1897-98; E. Thompson 1897a-b, 1898, 1904; Tozzer 1907, 1911; Tozzer and Allen 1910; Valentini 1879; Waldeck 1866.

APPENDIX 1.2

LIST OF WRITINGS RELATING TO THE ARCHAEOLOGICAL SITES MENTIONED IN THIS REPORT

Chichén Itzá: Arnold and Frost 1909, Chapter 6; Bancroft 1875-76:4:220-236; Charnay 1888, Chapter 18; Holmes 1895-97:101-137; Landa 1864:340-346; Maudslay 1889-1902:3:1-43, Plates 1-66; Morley 1911a; Relación de la ciudad de Valladolid 1900:13:3-40, 90; Stephens 1843:2: Chapters 16-17. Copán: Bancroft 1875-76:4:77-105; Gordon 1896, 1898, 1902; Maudslay 1889-1902:1:1-69, Plates 1-119; Morley 1911; Stephens 1841:1: Chapters 5-7. Labná: Arnold and Frost 1909:193-196; Stephens 1841:2: Chapter 3; E. Thompson 1897. Mayapán: Stephens 1843:1:130-141. Naranjo: Maler 1908:80-127, Plates 20-44. Palenque: Bancroft 1875-76:4: Chapter 6; Charnay 1888, Chapters 13-14; Holmes 1895-97:1:151-209; Maudslay 1889-1902:4:1-38, Plates 1-93; Stephens 1841:2: Chapters 17-20; Waldeck 1866; Río 1822. Piedras Negras: Maler 1901:40-75, Plates 7-33. Quiriguá: Hewett 1911, 1912; Maudslay 1889-1902:2: 1-19, Plates 1-66; Morley 1912, 1913; Stephens 1841:2: Chapter 7. Seibal: Maler 1908:1-28, Plates 3-10. Tikal: Bancroft 1875-76:4:135-138; Charnay 1888:464-473; Maudslay 1889-1902:3:44-50, Plates 67-82; Tozzer 1911. Uxmal: Charnay 1888: Chapter 20; Holmes 1895-97:1:80-96; Morley 1910a, 1911b; Stephens 1841:2: Chapters 24-25; Stephens 1843: Chapters 7,8,10,11,14. Yaxchilán: Charnay 1888: Chapter 22; Maler 1903: Chapter 13, Plates 39-80; Maudslay 1889-1902: 2:40-47.

APPENDIX 1.3

INCOMPLETE LIST OF GROUPS OF RELATED STRUCTURES AT CHICHÉN ITZÁ, YUCATÁN

1. The Monjas Group.
The Main Range.
The East Wing.

- The L-shaped Annex.
 - The Southeast Temple.
 - The Iglesia (church).
 - The Caracol (snail, winding stairway). This structure has an interior spiral stairway.
 - The Casa Colorado. A small nameless temple, and about a dozen other structures now in ruin.
2. The Akatzib (writing in the dark), named after a hieroglyphic inscription in a dark, interior chamber.
 3. The Group of the High Priest's Grave.
 - The Temple of the High Priest's Grave.
 - The Temple of the Atlantes and four or five other structures now in ruin.
 4. The Castillo Group.
 - The Castillo.
 - The Temple of the Cones.
 - The Sacred Way leading to the Cenote of Sacrifice.
 - The small temple on the edge of the Cenote of Sacrifice.
 5. The Ball-Court Group.
 - The Ball Court.
 - The North Temple.
 - The South Temple.
 - The Temple of the Jaguar.
 - The Lower Chamber of the Temple of the Jaguars, and five or six other structures now in ruin.
 6. The Group of the Column.
 - The Temple of the Tables.
 - The Temple of Chac Mool¹⁷
 - The Small Ball Court no. 1 (?)¹⁸
 - The Small Ball Court no. 2 (?)
 - The Peristyle (this imposing structure surrounds a court of over five acres).
 - The Temple of the little Tables.
 - The Temple of the Stairway.
 - The Sunken Court, and many smaller peristyles, temples, and pyramids. This group covers more ground and contains more structures than any other in the city.
 7. The North Group (a mile [1.6 km] north of the Cenote of Sacrifice).
 - The Temple of the Butterfly.
 - The Temple of the Jaguars no. 2.
 - The Causeway leading to "The Cenote of Sacrifice," and several other structures now in ruin.
 8. The Group of the Temple of the Initial Series (Old Chichén Itzá).
 - The Temple of the Initial Series.
 - The Temple of the Phalli.
 - The Temple of the Owl and a dozen other structures now in ruin.
 9. The South Group (a mile [1.6 km] south of the Monjas. Old Chichén Itzá).
 - The Temple of the Hieroglyphic Lintel.
 - Nameless temple.
 - Nameless temple.

10. The West Group (about a mile [1.6 km] west of the Monjas. Old Chichén Itzá).

This group contains a number of structures in an advanced state of ruin, which probably date from the earliest occupancy of the city. In addition to the foregoing, there are a number of other groups of related structures at Chichén Itzá, too ill-defined to describe here, some of which are as much as 6 miles [9.7 km] distant from the center of the city.

APPENDIX 1.4 DESCRIPTION OF HUMAN SACRIFICES AT "THE CENOTE OF SACRIFICE," CHICHÉN ITZÁ, YUCATÁN

The following description of human sacrifices at "The Cenote of Sacrifice" is taken from a letter written by three of the original conquistadores of Yucatán, and is part of a general description of Chichén Itzá. This letter was written in response to a general circular sent out by the Council of the Indies in 1579, asking for information about the discovery and conquest of the colonial possessions, and about the native inhabitants thereof.

At this cenote, the lords and chiefs of all the provinces of Valladolid observed this custom. After having fasted for 60 days without raising their eyes during that time even to look at their wives, nor at those who brought them food, they came to the mouth of this Cenote and, at the break of day, they threw into it some Indian women, some belonging to each of the lords, and they told the women that they should beg for a good year in all those things which they thought fit, and thus they cast them in unbound, but as they were thrown headlong, they fell into the water, giving a great blow on it; and exactly at midday she who was able to come out cried out loud that they should throw her a rope to drag her out with, and she arrived at the top half dead, and they made great fires round her and incensed her with Copal, and when she came to herself she said that below there were many of her nation, both men and women, who received her, and that raising her head to look at some of them they gave her heavy blows on the neck, making her put her head down, which was all under water, in which she fancied were many hollows and deeps; and in answer to the questions which the Indian girl put to them, they replied to her whether it should be a good or bad year, and whether the devil was angry with any of the lords who had cast in the Indian girls, but these lords already knew that if a girl did not beg to be taken out at midday, it was because the devil was angry with them, and she never came out again. Then, seeing that she did not come out, all the followers of that lord and

the lord himself threw great stones into the water, and with loud cries fled from the place.

APPENDIX 1.5 DESCRIPTION OF THE AZTEC BALL GAME *TLACHTLI*

The following description of the Aztec ball game, *tlachtli*, is taken from a general account of the diversions of Montezuma and his court, by Antonio de Herrera, in *Historia general de los hechos de los Castellanos en las islas i tierra firma del Mar oceano* (Madrid, 1726–30. 5 v.). As the ballcourt at Chichén Itzá is known to have been of Nahua origin, it is probable that this same game, or at least one very similar, was played there.

The king took much delight in seeing sport at ball, which the Spaniards have since prohibited, because of the mischief that often happened at it; and was by them called *tlachtli*, being like our tennis. The ball was made of the gum of a tree that grows in hot countries, which, having holes made in it, distils great white drops that soon harden, and, being worked and molded together, turn as black as pitch. The balls made thereof, though hard and heavy to the hand, did bound and fly as well as our foot-balls, there being no need to blow them; nor did they use chaces, but vied to drive the adverse party, that is, to hit the wall, the others, were to make good, or strike it over. They struck it with any part of their body, as it happened, as they could most conveniently; and sometimes he lost that touched it with any other part but his hip, which was looked upon among them as the greatest dexterity; and to this effect, that the ball might rebound the better, they fastened a piece of stiff leather on their hips. They might strike it every time it rebounded, which it would do several times, one after another, insomuch that it looked as if it had been alive. They played in parties, so many on a side, for a load of mantles or what the gamesters could afford, at so many scores. They also played for gold and feather-work, and sometimes played themselves away, as has been said before. The place where they played was a ground room, long, narrow, and high, but wider above than below, and higher on the sides than at the ends, and they kept it very well plastered and smooth, both the walls and the floor. On the side walls they fixed certain stones, like those of a mill, with a hole quite through the middle, just as big as the ball, and he that could strike it through there won the game; and in token of its being an extraordinary success, which rarely happened, he had a right to the cloaks of all the lookers-on, by ancient custom and law amongst gamesters; and it was very pleasant to see, that as soon as

ever the ball was in the hole, the standers-by took to their heels, running away with all their might to save their cloaks, laughing and rejoicing, others scouring after them to secure their cloaks for the winner, who was obliged to offer some sacrifice to the idol of the tennis-court, and the stone through whose hole the ball had passed. Every tennis court was a temple, having two idols, the one of gaming, and the other of the ball. On a lucky day, at midnight, they performed certain ceremonies and enchantments on the two lower walls and on the midst of the floor, singing certain songs, or ballads; after which a priest of the great temple went with some of their religious men to bless it; he uttered some words, threw the ball about the tennis-court four times, and then it was consecrated, and might be played in, but not before. The owner of the tennis-court, who was always a lord, never played without making some offering and performing certain ceremonies to the idol of gaming, which shows how superstitious they were, since they had such regard to their idols, even in their diversions. Montezuma carried the Spaniards to this sport, and was well pleased to see them play at it, as also at cards and dice.

NOTES

1. By *Inca* is here meant the people who dominated Peru at the time of the Spanish Conquest. The Inca civilization, like the Aztec, was of comparatively recent origin, not extending back more than three or four centuries before the first coming of Europeans in 1525.

2. For a brief bibliography of the Maya civilization and culture area see Appendix 1.1.

3. These large natural wells, often 200 feet [61 m] in diameter, and called by the Maya cenotes.

4. Victoria Peak, In the Cockscorn Mountains of British Honduras, in said to reach this elevation.

5. For the location of them sites and for a description of them, as well as the others mentioned in this report, consult the references given in Appendix 1.2.

6. This particularly true of the Ball Court, which is a purely a Nahua type of building.

7. This expedition, however, was not the first appearance of white men on the shores of Yucatán. In 1511 a caravel, bearing the regidor Valdivia from Darien to Española (Cuba), was wrecked near Jamaica, and all aboard were lost, except Valdivia and about 10 companions, who took to a small open boat. After untold suffering, during which half of them died, the miserable survivors were cost upon the eastern coast of Yucatán, where they were seized by the Maya, thrust into prison, and held for sacrifice. One by one they were killed until only a half dozen were left. These rendered desperate by the cruel fate of their comrades, broke out of their prison one dark night and fled to a neighboring village whose lord was not so bloodthirsty. Here they were enslaved. In the course of time all but two died, Geronimo de Aguilar and Gonzalo Guerrero. The

former, after eking out a miserable existence for eight years, was rescued by Hernán Cortés in 1519, and lived to play an important role in the conquest of Mexico as one of Cortés' two interpreters. Gonzalo Guerrero had even a more picturesque career. He exhibited such proficiency in military affairs that his master a Maya lord, put him in charge of his army. His successes here won him an Indian wife of noble blood, by whom he had several children. He became a Maya in every respect, covered his body with tattooing, allowed his hair to grow, pierced his ears for earrings, and as the pious chronicler concludes: "It is even believed he was an idolater like them" (Landa 1864:16).

8. These two theaters appear just north of the Castillo. They were probably used for performing certain religious rites, more or less public in character, and were theaters only in that limited sense.

9. The Maya Renaissance took place during the tenth century, or after the close of the Transitional Period in 960 AD.

10. The Initial Series method of recording dates has been so named because when it is present it always stands at the beginning of an inscription. It denotes, by means of five time periods, the number of days which have elapsed from the starting point of Maya a chronology to the date recorded. It is interesting to note in this connection that practically all of the southern Maya cities flourished during Cycle 9 of their epoch or about 3,500 years after the starting point. This long gap between the starting-point and the first recorded dates clearly indicates the hypothetical nature of the starting-point, a parallel case being that of Bishop Landa's date of 4004 BC for the creation of the world. The Maya doubtless developed their complex chronological system 2,000–3,000 years after the date which they selected for its starting-point.

11. The *u kahlay katunob* (Maya for "record of the katuns") is, as its name signifies, a record of the katuns, a Maya time period containing 7,200 days or nearly 20 years (19.71+). In the *u kahlay katunob*, the katuns were regarded as following each other in an endless sequence since the beginning of the record, and events were described as having occurred in such and such a katun.

12. John G. Owens, a member of the Peabody Museum of American Archaeology and Ethnology, Harvard University, expedition died of tropical fever at Copán in 1893. He was buried at the foot of the Hieroglyphic Stairway. In 1912 Earl Morris inscribed Owens' name and date of death on a large stone slab [ed.].

13. At Quiriguá the native laborer at 75 cents a day was so inefficient as to be actually more costly than the imported Carib laborer at \$1.00 a day.

14. The writer has had experience with both the Maya and Guatemalteco, and has found the former to be about twice so capable and efficient in the latter.

15. A case in point is the Monjas. This building clearly dates from several different epochs [...] Several styles of decoration appear in the four or five different additions, which together make up the building, and excavation would doubtless establish their chronological sequence. This chronological sequence of style, once determined, would serve as a guide in establishing the relative ages of buildings which show only a single style of decoration.

16. While the writer believes at least 20 years would be necessary to complete satisfactorily a definite research in the Maya field, it is not to be supposed, on that account, the intensive investigations for a shorter period would be devoid of important results. It is highly probable that much valuable scientific data would be gathered during a 10 years' study of Chichén Itzá, though such a period of research would by any means exhaust the possibilities of the site. The point which this writer wishes particularly to emphasize is that, to complete a large and definite research at Chichén Itzá and its environs, 20 years at least will be required.

17. This name has been applied to a class of sculptures at Chichén Itzá, which represents a human being, partially reclining, lying on its back; the knees and elbows are raised, and the feet drawn in; the head is elevated and turned to one side; the hands hold a bowl for burning incense. One of these Chac Mools was found in front of this temple, hence its name: The Temple of Chac Mool.

18. The identification of these two structures as Ball Courts is not certain, though probably correct. Excavation would doubtless clear up this point.

1.2.

SYLVANUS G. MORLEY

Archaeology

YB 13:333, 1914

After conferences in July 1914 with the President [Robert S. Woodward] of the Institution, Mr. Morley proceeded to Santa Fe [New Mexico] to take up the preparation of a work containing descriptions and decipherments of all known Maya texts, which will be so arranged as to be a ready and standard book of reference on Maya chronology.

The Maya hieroglyphic inscriptions, so far as they have been deciphered, deal exclusively with the counting of time either in relation to the Maya calendar or certain astronomical phenomena with which the Mayas were familiar. Especially important are the so-called Initial Series, which fixed dates in the Maya chronological system in such a way that they could not recur, filling all the given conditions, until after a lapse of 374,400 years. During the past five years at least 50 new Initial Series have been discovered which have never been published; and when it is taken into consideration that only about 90 had been previously described, it seems probable that the investigation of the new material already in hand, as contemplated in this research, will shed much light on the whole field of Maya chronology and clear up many existing problems.

1.3.

SYLVANUS G. MORLEY
Archaeology

YB 14:343–346, 1915

In December 1914 Mr. Morley submitted a report to the President [Woodward] suggesting the advisability of further field work at certain centers of the Maya civilization, notably La Honradez and Cancuen in northern Guatemala, and Copán in western Honduras, before the publication of his report on the Maya hieroglyphic inscriptions then in course of preparation. This report having been approved, he came to Washington in January to arrange the details of the trip and to secure the necessary outfit therefore. It was planned that he should visit the three sites mentioned (and such others as he deemed pertinent to the object of the research); and that he should secure whatever additional data might be necessary for a complete presentation of their hieroglyphic texts.

In execution of this plan, Mr. Morley sailed from New Orleans for Belize, British Honduras, early in February, accompanied by Mr. J. P. Adams as assistant.

The itinerary followed is shown in Figure 1.3.1. It divides conveniently into three parts, the objective in each case being one of the three sites mentioned above.

The first trip from Belize to the ruins of La Honradez and return took three weeks. The route lay at first up the Belize River to El Cayo, and thence northward through the dense tropical forests of northern Guatemala to La Honradez. The country is virtually a trackless jungle, the only inhabitants being a few mahogany cutters and chicle bleeders. The operations of the former are confined exclusively to the immediate vicinities of the few navigable streams, but the latter have traversed the bush hinterland in every direction in search of chicle, the principal ingredient of chewing-gum. Indeed, is chiefly due to the activities of the *chiclero* that new archaeological sites are discovered from time to time and that the intensive study of the antiquities of the region is made possible.

The second trip, to the ruins of Copán in the western part of Honduras, lay in a different direction. On March 15 the expedition sailed from Belize for Puerto Barrios, Guatemala, thence by rail inland to Zacapa, thence by mule-train two days' journey eastward to Copán. This region is entirely different in character from the densely forested, gently rolling plains of northern Guatemala. It is traversed by ranges of high mountains, whose steeply sloping sides and the valleys at their feet are all cleared and under cultivation, chiefly in coffee. Much tobacco is also grown, the Copán Val-

ley, in which the ruins are located, being particularly famed for the superior quality of its leaf, said to be equal that of the finest Havana tobacco. This site was one of the largest centers of the ancient Maya world, and is particularly rich in hieroglyphic texts, perhaps as high as 35 percent of all known Maya inscriptions being found here. The copying and photographing of this material, much of which is new, consumed five weeks and the expedition did not return to Puerto Barrios until the last of April.

The third and last trip was the most difficult. The route lay from Puerto Barrios to Livingston and thence up the Golfo Dulce and Río Polochic to Panzos, and thence by mule-train to Cahabón, in the department of Alta Vera Paz, one of the richest coffee-producing states in Guatemala. There are no mule-trails beyond Cahabón, and from this point it was necessary to proceed on foot, the baggage being borne by Indian carriers.

After a week's journey through the bush in a north-westerly direction, the ruins of Cancuen on the Río de la Pasión were reached, and here the Indian carriers

Figure 1.3.1. Itinerary of the 1915 Central American Expedition.

Figure 1.3.2. Map Illustrating Archaeological Investigations in Mexico and Central America (the circle encloses the region occupied by the Maya civilization).

turned back. After an examination of this little-known site and the discovery of a new altar there the journey out was commenced on May 14.

The expedition proceeded down the Río de la Pasión in a mahogany dugout to Sayaxché, the headquarters of the American and Guatemalan Mahogany Export Company, and thence by mule-train to Flores, the picturesque little island-city on the Lake of Petén Itzá, visited by Hernán Cortés in 1525 on his memorable and tragic march from Tabasco to the Gulf of Honduras.

After resting here a few days, the journey out to the coast was resumed, and on June 5 the expedition returned to Belize, thus closing a loop of over 1,000 miles [1,610 km] of mule, foot, and motor-boat travel, which had taken three months almost to a day. In addition to the three sites, an examination of which was contemplated in the original plan, nine other ruin-groups were visited, as follows: Quiriguá, La Reforma III, Seibal, Itsimté, Flores, San José de Motul, Yaxhá,

Benque Viejo, and Nakúm; and new material were obtained at each.

The results, arising from the study of the various inscriptions at the foregoing 12 sites, may be summarized as follows:

First and most important, seven new dated cities have been added to the 19 previously known, an increase of nearly 37 percent in this direction, as follows: 1. La Honradez, 2. Cancuen, 3. Itsimté, 4. Flores, 5. Yaxhá, 6. Nakúm, and 7. Benque Viejo. The distribution of these is shown in Figure 1.3.3, where the newly dated cities are represented by black dots and those the dates of which were previously known by crosses.

Four new monuments were discovered: a stela at Seibal, an altar at Cancuen, and an altar and a rock-cut shrine at Copán.

Eight new Initial Series were discovered: four at Copán, three at Itsimté, and one at Yaxhá.

Ten new period-ending dates were discovered: two at Copán, two at Cancuen, two at Flores, two at Nakúm,

Figure 1.3.3. Diagram Showing Distribution of the New Chronological Material Gathered by the Carnegie Institution Expedition in 1915 (new dates are in outline, previously known dates in solid black).

one at Seibal, and one at Benque Viejo. In addition to the foregoing, a large number of "corrected readings" of previously deciphered texts, as well as new readings of previously reported but heretofore undeciphered texts, were secured. Many of the earlier readings were found to be inaccurate, and a thorough revision of all previous decipherments was undertaken.

The general relation of this new material to the whole subject of Maya chronology is set forth graphically in Figure 1.3.3. This figure shows the several periods of occupancy of the different southern cities based upon the dated monuments at each.

The successive 20-year periods of the Maya era appear across the top of the figure, there being 20 years (7,200 days) between any two adjacent heavy black lines, that is, from 9.0.0.0 to 9.1.0.0 for example, and five years (1,800 days) between any two adjacent lines. The new dates appear in outline, previously known dates being shown in solid black.

It will be seen in Figure 1.3.3 that all of the new dates, except the one from Yaxhá, occur during the Great Period; and that not a few fall at its very close from 10.1.0.0 to 10.2.0.0 (580–600 AD). This is perhaps the most important single contribution of the expedition; that is, the accumulation of data tending to

show that the Old Empire made its final stand in the northeastern corner of Guatemala, in what is now the Department of Petén at the cities of Seibal, Flores, Tikal, Ucanal, Benque Viejo, Nakúm, and Naranjo.

In the extreme south, at Copán and Quiriguá, and in the west from Palenque southeastward, including the long chain of cities on the Usumacinta River (Piedras Negras, El Cayo, Yaxchilán, El Pabellon, Altar de Sacrificios, and Aguas Calientes) the practice of setting up monuments appears to have ceased by the end of Cycle 10, that is, 10.0.0.0; and the inference is reasonable that these centers had either been abandoned outright, or at least had sunk to such a low level of cultural activity as to be incapable of artistic and chronological expression. Only in the northeastern part of Petén the light of culture was kept burning for a half century longer, to be extinguished finally by the great exodus which put an end to the Old Empire about the beginning of the seventh century AD.

The swiftness with which the closing catastrophe fell, whatever may have been its nature, is apparent from the fact that not a single city of the Old Empire has a date later than 10.2.0.0, although a number of cities were surely occupied down to this time or 20 years prior thereto.

1.4.

SYLVANUS G. MORLEY

Archaeology

YB 15:337–341, 1916

During the summer and fall of 1915 work on the inscriptions of Copán, Honduras, was continued. After returning from the field in June, Mr. Morley proceeded to Cambridge to examine the original texts, casts, and photographs in the Peabody Museum, Harvard University, and to incorporate this material with the results of his previous studies in a forthcoming monograph on the inscriptions at this site (Morley 1920).

The 1916 Central American Expedition took the field early in the year, sailing from New Orleans for Puerto Barrios, Guatemala, on February 3 and returning to this country on June 5. During this period the personnel of the party changed several times. After the highlands trip, Mr. A. W. Carpenter became photographer and continued in this capacity until the close of the season.

Dr. George Underhill was the expedition physician for the Copán and Tulúm trips, and Dr. Moise Lafleur for the Uaxactún trip. The tragic death of the latter and of a guide, on May 17, in northern Petén, has already been made the subject of a special report to the President of the Institution [Carpenter 1950].

In addition to the foregoing regular members of the staff, the expedition was peculiarly fortunate in having the services at one time or another of several other collaborators who materially increased the range of activities. Mr. W. H. Holmes, Head Curator of Anthropology at the U. S. National Museum, accompanied the party to the ruins of Copán and made an archaeological panorama of the site, which he has kindly placed at the disposal of the Institution. Mr. S. K. Lothrop, of Harvard University, was with the expedition until the end of March. He made a number of maps and plans, including a survey and archaeological panorama of the ruins of Tulúm. Dr. T. Gann, chief medical officer of British Honduras, made the Tulúm trip for the purpose of copying the extensive mural paintings there, an excellent representative series of which was secured.

The itinerary of the expedition may be divided into four parts or trips, each corresponding to a well-defined unit of work: 1. the highlands of Guatemala; 2. the ruins of Copán; 3. the ruins of Tulúm, on the east coast of Yucatán, Mexico; 4. the ruins of Uaxactún, northern Petén, Guatemala.

The objectives of the first trip were the ruins of Chinkultic and Ocosingo in the State of Chiapas, Mexico,

where hieroglyphic inscriptions have been reported by Seler and others. Owing to the revolutionary disturbances in this region, however, it was impossible to proceed beyond Huehuetenango in the highlands of Guatemala, and the party returned to the capital without having reached either of its destinations.

The Copán trip was more successful. Several new inscriptions, chiefly fragmentary texts from the Archaic period, were discovered and copied. The most notable find, however, was that of a heretofore unreported stela, which was located in the walls of the cabildo at Santa Rita, a small village seven miles [11.3 km] up the valley from the main group of ruins. Its several pieces were removed from this exposed position, and after the inscription had been copied and photographed, they were carried to a place of safety. The new monument, to which the number 23 has been given, dates from the early part of the Middle Period 9.11.0.0.0, approximately 380 AD.

The third trip, to Tulúm on the east coast of Yucatán, was exceedingly fruitful. This site has long held a peculiar interest for students in the Maya field, not only because of its size and individuality, but also on account of its comparative inaccessibility and isolation.

It was first described by the American traveler Stephens, in 1840 (Stephens 1841:2:385–409), though owing to the War of the Castes, which ravaged Yucatán in 1848, it has since been closed to investigation. Maya Indians, fleeing from the victorious Mexicans in the western part of the peninsula about the middle of the last century, settled in the region around Tulúm, where they have maintained themselves in virtual independence ever since. They have successfully resisted such Mexican troops as have been sent against them, falling back into the bush before large parties and killing such small parties as have ventured into their country.

Only twice since Stephens's time has the site been visited, once by an expedition from Harvard University in 1911, and once by an expedition from the School of American Archaeology in 1913. Neither party stayed at the ruins for more than 24 hours, and beyond a brief reconnaissance, little was accomplished by either.

Several circumstances made the present season especially opportune for visiting the site. Friendly relations have been established between the Mexican government and the Maya for the first time in many years. The expedition was at Belize, the best point from which to make the trip; and finally the party was sufficiently numerous, five investigators and assistants, to insure an adequate study of the site in a minimum of time. A small steamboat, of about 40 tons, was hired at Belize and the expedition sailed for Tulúm on March 19.

The most important result was the location of the hieroglyphic monument first reported by Stephens, and later by Howe of the Peabody Museum expedition. Howe's reading of the date as 9.6.10.0.0, approximately 290 AD (Howe 1911), was verified and drawings and photographs were made. The occurrence of such an early date as 290 AD at such a late Maya site as Tulum is difficult to explain. Geographically, architecturally, stylistically, and historically considered, Tulum is a thousand years later than the Initial Series date of this stela. Indeed, barring this one date, there is nothing at Tulum to connect it with the Old Empire; on the contrary, its location, architecture, and mural decoration strongly indicate that it is to be referred to the close of the New Empire, probably some time after 1200 AD. The question is an important one, and further investigation will be necessary before this apparent anachronism can be satisfactorily explained and the discrepancy between the chronological and other criteria cleared away.

Dr. Gann secured tracings of a number of the mural paintings and made the necessary color notes for their accurate reproduction. In the time available, however, it was impossible to make more than a beginning upon this important work. The subjects portrayed are exclusively of a religious nature, representations of the principal deities of the Maya pantheon in various acts of sacrifice. God B of the Schellhas classification, probably the chief Maya divinity, occurs repeatedly. The delineation of the figures so closely resembles that in the Codex Tro-Cortesiano as to strongly suggest that this manuscript originated not far from Tulum.

A map of the religious and civic center of the city, that is, the area within the walls¹ was prepared by Mr. Lothrop, as well as elevations and ground-plans of all the more important structures. The archaeological panorama already mentioned was based upon these data and conveys an excellent idea of the city as it once appeared.

The foregoing material, together with the photographic record secured by Mr. Carpenter, now makes possible for the first time the preparation of an adequate preliminary report of this little-known site and paves the way for its more intensive investigation.

The last trip, to northern Petén, was the most profitable of the season, resulting in the discovery of a large new city and the oldest monument yet reported from the Maya field. This site, to which the name Uaxactún was given,² is of major influence. Although less extensive than the largest Maya cities, Tikal, Copán, Chichén Itzá, and Uxmal, it may be classed with such noteworthy sites as Quiriguá, Naranjo, and Nakúm, and was easily a center of large population.

Time and facilities were lacking for the thorough exploration of the region, so proximate was the rainy

Figure 1.4.1. Stela 9, Uaxactún (The earliest monument yet reported from the Maya area (approximately 50 AD); and the only stela known dating from Cycle 8 of the Maya chronological era).

season and so dense the tropical forests, but three large architectural complexes were located in an area not over half a mile square [1.3 sq km]. Each contained numerous courts, surrounded by the remains of extensive buildings, both of the dwelling and religious types, that is, palaces or monasteries and temples, and many monuments.

Group A, the first discovered, has five sculptured stelae and 10 plain ones; Group B has four sculptured stelae and 14 plain ones; and Group C has two sculptured stelae and four plain ones, a total of 39, and without doubt further investigation would bring others to light. The main plaza seems to have been at Group B, and here the most important monuments as well as the largest pyramid-temple were found. The most important monument is easily Stela 9 at Group B, which was found to record a Cycle 8 Initial Series as follows: 8.14.10.13.15, approximately 50 AD.

Stela 9 is the first and only monument yet reported which may safely be referred to Cycle 8 of the Maya chronological era, all others dating from Cycle 9 or 10; and it is therefore the earliest monument known.³ The carving is extremely archaic in character, note the

irregularity of the glyphic outlines, and the relief has suffered greatly from erosion. Fortunately the Initial Series is sufficiently preserved to decipher.

Of the 11 sculptured stelae found, seven have Initial Series; one has a Calendar Round date, and three are too effaced or broken to be determined. It is possible to decipher four of the seven Initial Series to the day, as [shown in Table 1.4.1].

Table 1.4.1. Calendrical Decipherments, Initial Series Dates, Uaxactún.

Monument	Date in Maya Chronology	Approximate Date in Christian Chronology
Stela 2	9.16.0.0.0 2 Ahau 13 Tzec	480 AD
Stela 3	9.3.13.0.0 2 Ahau 13 Ceh	230 AD
Stela 7	9.19.0.0.0 9 Ahau 18 Mol	540 AD
Stela 9	8.14.10.13.15 8 Men 8 Kayab	50 AD

Between the dates of Stelae 9 and 7 nearly five centuries elapsed, the longest recorded occupation of any Old Empire site.

Approximate readings of the remaining three Initial Series, Stelae 1, 5, and 6, have also been attempted. Stela 5 apparently records another Cycle 8 date, the best reading being 8.15.10.3.12, although this is open to considerable doubt. Stela 6 may certainly be referred to the Archaic Period, probably to Katuns 6, 7, 8, or 9, and Stela 1 with equal certainty to the Great Period, the best reading being 9.14.0.0.0.

The great importance of this new site lies in the number of its very early inscriptions. Stela 9 is the oldest dated monument known, and Stela 3 is the fourth oldest; and it is to be expected that other early texts will be found in the vicinity. The region is new territory, having been penetrated for the first time by chicleros less than three years ago. Other important sites are known to exist beyond Uaxactún, at least one having large standing buildings and sculptured monuments. The important bearing this site, and indeed the whole adjacent region, may have on the much-vexed question of the origin of the Maya civilization in its historical context, is readily apparent, and its further investigation is strongly recommended.

NOTES

1. The city is enclosed on three sides by a high wall, the bluff along the sea protecting the fourth side. This wall encloses an area of some 22 acres [0.089 sq km]. It varies from 8 to 13 feet [3.9 m] in thickness at the base, and from 10 to 15 feet [3.1–4.6 m] in height. The north and south

sides are pierced by two gateways and the west side by one.

2. The Tuxtla statuette and the Leyden plate are not included in the above statement. Although both record earlier dates than Stela 9 (8.6.2.4.17 and 8.14.3.1.12 respectively) neither is a monument, and neither, properly speaking, was found *in situ*. The Tuxtla statuette is a little figurine of nephrite, about 7 inches [17.8 cm] high, found near San Andrés Tuxtla, Mexico; and the Leyden plate is a plaque of the same material and of about the same length, which was found on the Río Graciosa near Puerto Barrios, Guatemala. Neither can be regarded as a large stone monument in the sense used here.

1.5.

SYLVANUS G. MORLEY

Archaeology

YB 16:285–289, 1917

During the autumn, winter, and spring of 1916–17 work was continued on the inscriptions of Copán, Honduras, and was brought almost to a close. An examination of all the available texts was completed, and there remains only the preparation of a concluding chapter, appendices, index, and tables. This work was suspended in April, when the 1917 Central American Expedition took the field, sailing from New Orleans for Puerto Barrios, Guatemala, on April 26, under instructions to make an archaeological reconnaissance of Central America, so far as that might be practicable. Mr. Morley was accompanied by Mr. John Held, Jr., of New York, as artist, and the expedition will remain in the field indefinitely.¹

The first trip was an archaeological reconnaissance of western Honduras, the itinerary of which is shown in Figure 1.5.1, together with the locations of the new sites discovered. The expedition left Zacapa, Guatemala, on May 15, going first to the ruins of Copán, Honduras, where several days were spent in drawing and photographing the new texts, which had been discovered since the previous visit in March 1916. One of these, a fragmentary stela, to which the number 24 was given, proved to be the earliest monument yet found at this site, recording the date 9.2.10.0.0 of the Maya era, or approximately 210 AD.

The circumstances surrounding the discovery of this particular fragment are of special interest because of the light they shed upon a common Maya practice throughout the period of the Old Empire, namely, the

Figure 1.5.1. Itinerary of the 1917 Central American Expedition.

re-use of earlier monuments in later constructions. This piece was found near the southwestern corner of the village plaza, 3 feet [91 cm] below the present level of the ground. It rested directly upon the foundation stone of Stela 7, in the support of which it seems to have been used. But the date of Stela 7, in the support of which it seems to have been used. But the date of Stela 7 is 9.9.0.0.0 of the Maya era, approximately 340 AD; in other words, Stela 24 was broken up and re-used in the foundations of this later monument 130 years after the date upon which it was originally erected (210 AD). This practice was known to have been common during the Middle and Great Periods of the Old Empire, but the present case is the first example of its occurrence as far back as the Early Period.²

The front and back of Stela 24 are inscribed with hieroglyphs, the sides being left plain, though dressed smooth. The single fragment was recovered from about 3 feet [91 cm] below the surface and presents the cycle, katun, tun, uinal, and day signs, all perfectly preserved and permitting the certain decipherment of the date as given above.

Another interesting point in connection with this monument is that it records a half katun end (lahuntun), just like Stelae 15 and 9, the next two earliest monuments at Copán; furthermore, each is 40 years apart from the next. Indeed, it is probable that the marking of the first and third quarters of the katuns (hotuns) did not commence until later, about the close of the Early Period.³

Table 1.5.1. Calendrical Decipherments, Stelae, Copán.

Stela 24	9.2.10.0.0	ca. 210 AD
Stela 15	9.4.10.0.0	ca. 250 AD
Stela 9	9.6.10.0.0	ca. 290 AD

Stela 24 is three years earlier than the earliest date yet deciphered at Tikal and indicates that the antiquity of Copán, the southern Maya metropolis, may yet

to be found to exceed that of her great northern rival.⁴

A very fine altar of the Great Period, called W' was discovered in a small plaza about a half mile [0.8 km] east of the Main Group on the western bank of the river. The front was sculptured with a representation of the two-headed monster, and the back and sides with hieroglyphs. Many of the signs that are the unusual full-figure variants, and the dedicatory date would appear to have been the hotun ending 9.17.5.0.0, approximately 505 AD. Photographs and drawings were made of all four faces.

Two of the three missing fragments of the east altar of Stela 5 were also found during the past year in the bush just north of the stela. One of these presents Glyphs C, D, and E of the Supplementary Series. Photographs and drawings were made of the inscription.

The long missing fragment of a Great Period Initial Series, photographed by Maudslay in the eighties, was located in the foundations of a house on the southern side of the village plaza and was removed to the cabildo for safe keeping. This piece is chiefly important as presenting the latest example of an Initial Series yet found at Copán. Several other fragments, probably referable to the Early Period, were found, and also removed to the cabildo.

The next site visited was Santa Rita, 7 miles [11.3 km] up the valley from Copán, where Stela 23 was discovered last year [Chapter 1.4 this volume]. A drawing of one of the sides omitted last year was made, which completes the record of this text.

Figure 1.5.2. Los Higos, Stela 1; Copán, Stela 24. a. Stela 1, Los Higos, Honduras. This monument records the date 9.17.10.0.0 of the Maya era, or approximately 510 AD. It is the best style of the Great Period of the Old Empire, which was the golden age of Maya art; b. Stela 24, Copán, Honduras. This fragment of a monument presents the earliest date yet found at Copán, namely 9.2.10.0.0 of the Maya era or approximately 210 AD. One hundred and 30 years after its erection, it was broken up and used over again in the foundations of another monument.

The first of the two new sites discovered on this trip, Río Amarillo, is on the bank of the Copán River, about 12 miles [19.3 km] northeast of Santa Rita. A number of mounds are built on the side of a hill, which has been artificially terraced, and at the eastern end, near the base, are two hieroglyphic altars. Unfortunately, although the inscriptions are perfectly legible, neither presents a date in the Long Count; and it is therefore impossible to assign either to its exact position in Maya chronology. From the style of the carving, however, both are surely referable to the Great Period. It is to be regretted that not a single date can be deciphered here, although the approximate age of the site is doubtless determinable from the stylistic criteria. A map of the site, and drawings and photographs of both inscriptions, were made.

Leaving the Copán Valley and passing over the divide into the Chamelecón Valley, another new site was discovered at Los Higos, some 12 miles [19.3 km] northeast of the village of La Florida.⁵ This site is on the west side of the Chamelecón River and an eighth of a mile [1.3 km] back, at the base of the first foothills. It contains upwards of 30 mounds, including several fairly high pyramids and one very fine stela in the best style of the Great Period. The inscription is unusually well preserved and records the date 9.17.10.0.0 of the Maya era, approximately 510 AD. It is evident from this single piece of sculpture that the city derived its artistic inspiration from Copán; indeed, it was probably colonized from Copán during the Middle or Great Period. A map of the site was made, and the inscription was drawn and photographed.

One of the results of the past four years work in this part of the Maya field has been the rather definite

location of the eastern or southeastern Maya frontier.

During this period four new sites (Paraiso, Santa Rita, Río Amarillo, and Los Higos) have been added to the two previously known (Copán and Quiriguá) and the general historical development of the region has been worked out. A comparison of the earliest and latest dates at these six cities clearly establishes their relative ages.

Table 1.5.2. Chronological Development of Six Classic Maya Sites.

Copán	210–530 AD	
Santa Rita	380 AD	Only one date
Quiriguá	475–540 AD	
Río Amarillo	460–600 AD	Date based upon stylistic criteria
Paraiso	460–600 AD	Date based upon stylistic criteria
Los Higos	510 AD	Only one date

Copán was the first settlement in this region, possibly being founded as early as the first century before Christ. Although Santa Rita had been founded as early as the beginning of the Middle Period, 380 AD, it was not until the beginning of the Great Period, 100 years later, that the extensive colonization of the region really began. Quiriguá was founded in 475 AD or possibly 22 years earlier, and Los Higos was established shortly afterward, 510 AD.

Although it has been impossible to date either Paraiso or Río Amarillo exactly, both are certainly referable to the same general period on stylistic grounds, and we may accept the great extension of Maya dominion in the south as having taken place toward the close of the fifth century, beginning about 475 AD.

The frontiers of Maya esthetic influence doubtless overlapped the frontiers of actual empire in most places.

For example, the pottery of the Ulúa frontier, which lies considerably east of this chain of cities, shows unmistakable Maya influence. Also, during the present field season a large collection of pottery from north-western Salvador was found to contain many pieces almost exactly like those from the Copán tombs. Just as Rome influenced the life and art of the outer barbarians, so the Maya coerced the life and art of surrounding peoples of lower culture and imposed their esthetic standards and practices beyond the frontiers of their empire. The latter would appear to have been the chain of cities just described, whereas the former were strongly felt as far as the Ulúa Valley.

A second trip was made in Salvador and the central part of Honduras during July and August. Mr. Held made color drawings of the painted vases in the Justo Armas collection in San Salvador; and at Tegucigalpa he painted a magnificent specimen of Maya ceramic art from Copán. At San Pedro Sula a fine example of painted ware in the Waller Collection from the Ulúa Valley was also drawn in color. At Tegucigalpa occasion was taken to call upon His Excellency President Bertrand and Dr. Mariano Vásquez, the Minister of Foreign Relations, and to explain the work of the Carnegie Institution of Washington in Honduras, particularly at Copán. Friendly relations were established with these officials, and it is believed that the way was paved for more extensive work there in the future.

NOTES

1. During 1917 and 1918 Morley was an operative for the Office of Naval Intelligence hired to search for rumored German submarine bases along coastal Central America, to combat pro-German activities, and to organize a regional intelligence network. Other involved in this work included archaeologists Samuel K. Lothrop, Thomas Gann, J. Alden Mason, Herbert J. Spinden, the botanist Wilson Popenoe, and the cartoonist John Held (Harris and Sadler 2003:46 [ed.]

2. The Tuxtla statuette and the Leyden plate are not included in the above statement. Although both record earlier dates than Stela 9 (8.6.2.4.17 and 8.14.3.1.12 respectively) neither is a monument, and neither, properly speaking, was found *in situ*. The Tuxtla statuette is a little figurine of nephrite, about 7 inches [17.8 cm] high, found near San Andrés Tuxtla, Mexico; and the Leyden plate is a plaque of the same material and of about the same length, which was found on the Río Graciosa near Puerto Barrios, Guatemala. Neither can be regarded as a large stone monument in the sense used here.

3. The earliest first or third quarter of a katun now known is that recorded on Stela 25 at Piedras Negras, namely, 9.8.15.0.0, approximately 335 AD.

4. For further data relating to this question [see Chapter 1.4 this volume].

5. This site and monument were discovered through information furnished by Mr. Basil Booth, a mahogany contractor of Guatemala, and Mr. Samuel K. Lothrop, of the Peabody Museum of Harvard University.

I.6.

SYLVANUS G. MORLEY

Archaeology

YB 17:269–276, 1918

The Central American Expedition did not return to the United States during 1917, but remained in the field until the end of May 1918. Throughout this period the personnel of the staff continued the same: Mr. Morley as director and Mr. John Held, Jr., as artist. During the Yucatán trip, Dr. Thomas Gann, of Belize, accompanied the expedition as a collaborator, having filled a similar position with the 1916 expedition.

The itinerary of the expedition may be divided into three parts or trips, as follows: 1. A reconnaissance of the Mosquito Coast of Honduras and Nicaragua in September and November 1917. 2. An examination of all archaeological sites in the peninsula of Yucatán known to have hieroglyphic inscriptions, in February, March, and April 1918. 3. A trip to the ruins of Palenque in the state of Chiapas, Mexico, in May 1918. It may be noted also that Mr. Morley was present during the earthquake-shocks of December 25, December 29, and January 3, which destroyed Guatemala City, and he assisted in the relief work there [see Chapter 1.4 this volume].

The reconnaissance of the Mosquito Coast was undertaken primarily to establish how far eastward along the Atlantic littoral of Central America Maya esthetic influences may have extended, and it was a continuation of the work carried out in the summer of 1917, when the eastern frontier of actual Maya empire was somewhat definitely fixed as the Chamelecón Valley in Honduras.¹

At Tela, 35 miles [56.4 km] east of the mouth of the Chamelecón River, a beautiful clay head of purest Maya type was found, together with some fine flints and smaller objects. Further excavation, however, would be necessary here before it could be determined whether this head was of local origin, or whether it had been brought in by trade from farther west.

One hundred miles [161 km] farther east, at Trujillo, and on the Rincon peninsula, several sites were visited through the courtesy of Mr. H. D. Scott, superintendent of the Trujillo Railroad. These consist of deposits of potsherds, among which incised and modeled wares predominate, handles and animal's heads, fragments of tripod bowls, etc., and a few beautiful painted ware of the Ulúa Valley sites, which are themselves just west of the area of actual Maya dominion as established last year. One of these deposits on the right of way of the Trujillo Railroad, in a borrow-pit near the Aguan River, was fully 10 feet [3.1 m] below the present level of the ground, underneath a stratum of alluvial soil laid down by the river in one or more of its many wanderings over the flood-plain. Similar objects have been found on the adjacent Bay Islands, notably at Roatán and Guanajá, and it seems probable, from the preliminary examination, that this part of the coast and adjacent islands may be assigned to one and the same archaeological province, the culture of which was certainly inferior to that of the Maya and probably of subsequent origin as well.

East of the Aguan River no sites were found, although such may possibly exist in the dense bush behind the beach. From this vantage point eastward, moreover, the character of the country begins to change; the mountains draw away from the shore-line and finally disappear altogether, and there commences a series of shallow lagoons separated from the sea only by a low sandy strip of land. These and the surrounding marshes mark the edges of the great deltas of the Patuca and Wanks Rivers, and they were unadapted to the development of a high culture (Morley 1918).

The present inhabitants of this region are the Miskito Indians, a degenerate mongrel tribe in which Carib and possibly other strains appear. They are a simple fishing people, living in thatched huts along the banks of the lagoons and water-courses, with crude arts and crafts, among which stone carving is not included.

There are traditions of a more cultured tribe, the Sumus, who formerly occupied the region, but who long ago were driven back into the less desirable interior by the Miskito. Remnants of these older inhabitants of the littoral are still to be found several days' journey up the Patuca and Wanks rivers of eastern Honduras and northern Nicaragua.

It may be stated with reasonable assurance, although final proof must await further exploration and excavation, that proceeding eastward along the coast-plain evidences of high cultural activity fall off rapidly once the Ulúa River is left behind; also, that the Maya civilization proper does not seem to have exerted much influence east of this same valley.

The second trip, to the peninsula of Yucatán, was by far the most important of the year, and the results

obtained, through the discovery of the system of dating used in the northern cities, promise to shed a flood of light upon the little-known chronology of the New Empire. It has long been recognized that, after the Maya migrated northward from Guatemala and Honduras during the sixth and seventh centuries after Christ, into the peninsula of Yucatán, along with many another custom and practice, their system of recording dates also underwent considerable modification. The extraordinarily accurate Initial Series, for example, by means of which one day could be distinguished from any other in a period of 374,143 years, which had been so prevalent in the south, practically disappear in the north. Of the 150 odd Initial Series known, only three are found in Yucatán. Not only Initial Series, but all the other kinds of texts, become very much scarcer in the north. Indeed, in the whole peninsula there are only 12 sites known having as much as a single inscription, as compared with thrice that number in the south; and the whole content of these few constitutes less than 3 percent of the *Corpus Inscriptionum Mayarum* (Morley 1948).

Because of this scarcity of material, hardly offset by the few manuscript chronicles (the Books of Chilam Balam) that have come down to us. And because of our lack of knowledge as to the method of dating used, it followed that we knew much less of Maya history during the New Empire (600 AD to 1541 AD) than during the Old Empire (100 BC to 600 AD).

The immediate object of the second trip, therefore, was an examination of all known Yucatán sites having inscriptions, together with a first-hand study of the original texts, in the hope that some of this obscurity might be cleared away. The sites visited and their respective locations will be found on 1.6.2.

The results of this investigation was most promising, no less than the discovery of the system of dating used in the New Empire, as noted above. This was found to be a kind of Period Ending dating, and its discovery was made possible by the decipherment of the so-called "Winged-Cauac" glyph, which proved to be another variant of the tun sign. Mr. Morley had previously shown that the "Winged Cauac" had this meaning in the hotun sign (Morley 1915); and its extension to a more general use in Period Ending dating with coefficients other than 5, as already noted in the case of the hotun sign, was a logical development of Maya chronological practices.

The system was variously employed, the several methods in use depending for their varying degrees of accuracy upon the number of factors present. The simplest is merely the record of a given day falling in a given tun, for example, the day 6 Kan in Tun 9. As every Tun 9 contained one day 6 Kan, and some two such days, and as a Tun 9 recurred every 19.71 years,

Figure 1.6.1. Itinerary of the 1918 Central American Expedition (All sites shown above, with the exception of Chac Mool on the East Coast, have hieroglyphic inscriptions).

texts are fragmentary, enough remains of each to permit its decipherment, the dates of both being the same.²

A final modification of this last method is seen on the lintel from the north chamber of the western range of the Monjas Quadrangle at Uxmal, where not only the particular tun in which the date fell is given, but the particular katun as well. See Figure 1.4.1, where 5 Imix 19 Kankin is declared to have occurred in Tun 18 of Katun 13. By the addition of this last factor, accuracy within a period of 374,143 years was achieved. The more factors present, the more exact became the resulting date until the extreme accuracy of the Initial Series is equaled by this last method.

Although much remains to be done in working out the details of the new system, already it has been possible to decipher some new dates at different sites. These are given in Table 1.6.1, with the corresponding approximate equivalents in Christian chronology.

In addition to the foregoing dates recorded in the new system, several others recorded either as period endings, or calendar round dates, or in the *ukahlay katunob*, were displaced elsewhere.

The true date of the Temple of the Initial Series at Chichén Itzá is 10.2.10.0.0 2 Ahau 13 Chen, which makes it conform with the hotun hypothesis mentioned elsewhere. Previously this had been regarded as being 10.2.9.1.9 9 Muluc 7 Zac, that is, the Initial Series on the under side of the lintel. The contemporaneous date, however, is doubtless that recorded on the front of the lintel and is as given above.

Through the accidental discovery of an important missing fragment of the Tulum stela, it has been possible to date that monument as 10.6.10.0.0 7 Ahau 18 Yaxkin, that is, just one cycle later than its Initial Series 9.6.10.0.0 8 Ahau 13 Pax. That this Initial Series could hardly have been the contemporaneous date of the monument was noted in [Chapter 1.4 this volume], and elsewhere (Morley 1917); but the discovery of this fragment, which fits at the bottom of the inscription, gives a more satisfactory reading. Fortunately this important monument was not lost in the destructive hur-

this method was not very accurate. Happily it does not seem to have been much used much, occurring only once in the 16 cases under observation.

The commonest method (being used in half the cases) is the record of a given tun and the day upon which it ended, as for example Tun 13 ending on the day 2 Ahau. Such a date could not recur fulfilling all the given conditions until after a lapse of 256.26 days. As most of the New Empire sites were not founded until after 950 AD, and at the most were occupied less than 500 years, it is never necessary in such cases to distinguish between more than two possible readings, and usually only one is historically probable.

By the addition of the day of the month to the above method, as Tun 11 ending on the day 2 Ahau 18 Xul (a date found in the Temple of the High Priest's Grave at Chichén Itzá), accuracy within a far greater stretch of time was secured, no less indeed than within a period of 18,707 years.

A third method, which occurs in six out of the 16 cases, is far more accurate than even the preceding. It involves the use of a Calendar Round date with a given tun, ending on a given day. For example, 10 Ix 17 Pop falling in a Tun 17 ending on the day 12 Ahau. Such a date can not recur, fulfilling all the given conditions, until after the lapse of 243,193 years. An example of this kind is the inscription from the north sides of the rings in the ballcourt at Uxmal. Although both of these

Table 1.6.1. Calendrical Decipherments, Chichén Itzá, Uxmal, and Holactún.

Site	Building	Date in Maya Era	Corresponding Date in Christian Era
Chichén Itzá	Temple of the Two Lintels	11.7.12.16.18 9 Eznab 11 Yax	1107 AD
Chichén Itzá	Temple of the High Priest's Grave	11.19.11.0.0 2 Ahau 18 Xul	1350 AD
Chichén Itzá	Temple of the Owl (lintel)	12.2.13.0.0 1 Ahau 14 Ceh	1411 AD
Uxmal	Ball Court	11.15.16.12.14 10 Ix 17 Pop	1277 AD
Uxmal	Monjas Quadrangle, East Range, North Room	11.12.17.11.1 5 Imix 19 Kankin 11.2.8.4.9	1219 AD
Holactún	Temple of the Initial Series	7 Muluc 17 Tzec	1012 AD
Holactún	Temple of the Initial Series	11.2.13.0.0 2 Ahau 8 Yax	1017 AD

ricane of October 1916, as previously reported (Morley 1917:194).

Following Bishop Landa's statement that there were hieroglyphic monuments at Silan near the north coast (Landa 1864:52), the expedition visited this village and found fragments of two stelae, of which one had the Calendar Round date given above. This is but another of the many instances of the remarkable reliability of Bishop Landa's statements, which have been substantiated at every point by modern investigations in this field. The Mayapán date is from the stela found by Abbé Brasseur de Bourbourg, while digging at the site in the sixties of the last century. It is another corroboration of Bishop Landa, who had described hieroglyphic monuments here three centuries earlier. It is not improbable that this monument was the last katun stone to be erected at Mayapán, since the city was destroyed and abandoned before the expiration of the next 20 year period, that is, Katun 8 Ahau, when the next stone would have been erected.

One large new site was discovered on the east coast of the peninsula, between Asención Bay and Espíritu Santo Bay. It is about half as large as Tulúm and named Chac Mool, after an heroic-sized Chac Mool statue in stucco reclining under the arch or covered gateway leading to the principal temple.

The third and last trip of the season to the ruins of Palenque in northern Chiapas yielded little new material. Palenque has been more extensively visited than any other Maya site and its architecture and hieroglyphic inscriptions have been more adequately published (Maudslay 1889–1902).

Two new Initial Series were found, both in stucco; one on the left-hand pier of the façade of the Temple of the Sun, and the other on the back wall of the outer chamber of the Temple of the Beau Relief. Unfortunately

Figure 1.6.2. Chichén Itzá, High Priest's Grave (text engraved on front of a column. The date is expressed by the first and last two characters "2 Ahau 18 Xul ends Tun 11," which corresponds to the year 1350 AD).

both were entirely destroyed save for their introducing glyphs, and decipherment was impossible.

The large human statue which formerly stood in front of the Temple of the Cross, but now which lies on the southern slope of the substructure, has a single glyph carved upon its front. This is quite clearly the day 8 Ahau and in all probability denotes the katun ending 9.13.0.0.0 8 Ahau 8 Uo. This is also the latest date on the tablet of the Foliated Cross in the temple of the same name nearby, and on the tablet in the Temple of the Inscriptions across the stream, and is possibly to be interpreted as indicating that these three temples were all dedicated on the same day.

In spite of certain architectural evidence to the contrary, it seems fairly clear from the seven or eight dates now known at Palenque, that the city was at its zenith about 9.13.0.0.0 and not 100 years later, as has been suggested. Indeed, 9.13.0.0.0 is the latest date that has yet been found there. Beautiful as the Palenque sculptures are, possibly the best in the whole Maya area, their excellence may probably be ascribed to the superiority of the sculptural media, stucco or a very fine-grained limestone, rather than to a later period of ori-

Figure 1.6.3. Uxmal, Ball Court, text engraved on sides of the ballcourt rings. The same date is recorded upon each ring 10 Ix 17 Pop in Tun 17 ending on the day 12 Ahau, which corresponds to the year 1277 AD.

Figure 1.6.4. Uxmal, Monjas Quadrangle, Text Painted on a Capstone (The date is expressed by the first two characters in each line 5 Imix 19 Kank'in in Tun 18 of Katun 12, which corresponds to the year 1219 AD).

gin, and the city itself had probably already reached the zenith of its esthetic development before the beginning of the Great Period in 9.15.0.0.0.³

NOTES

1. Stone carvings of grotesque animal heads reported to have come from a site 5 to 6 days' journey up the Black River, just east of the Aguan River, were examined at Rincon. These are quite un-Mayan in character and suggest a local intensive development of stone-carving rather than an extensive distribution of the technique.

2. These two inscriptions may record a very important fact in New Empire chronology. It will be noted that while the corresponding day remains the same in each, that is, 10 Ix, on the left ring the month is apparently 16 Pop, and on the right ring it is 17 Pop, that is, a shift of one day in the month in the month coefficient. But this is precisely the degree of shift that occurred between the month coeffi-

cients of the Old Empire texts and the very late Books of Chilam Balam. In the Old Empire Ix has a corresponding month coefficient of 2, 7, 12, and 17, while in the Books of Chilam Balam it has 1, 6, 11, and 16. These two inscriptions, apparently recording the same date with this single difference, may possibly commemorate the fact that upon this date this important change was effected at Uxmal.

3. A correction should be noted here in the report of the previous year's work. [In Chapter 1.6 this volume] attention was called to the discovery of the ruins of Los Higos in the Chamelecón Valley, Honduras, through information derived from Mr. S. K. Lothrop, of Harvard University, and Mr. Basil Booth, of Guatemala City.

Credit for this discovery, however, it has been subsequently ascertained, belongs instead to the well-known Central American traveler, E. G. Squier (1883), who visited this site as early as 1850, and who seems to have published his first account thereof in *Frank Leslie's Magazine* for April 1883. Although he was unable to read the hieroglyphic inscriptions there, his visit having antedated by more than 30 years the first successful attempts at decipherment by Professor Ernst Förstemann and J. T. Goodman, Squier's priority of discovery remains unquestioned and any credit arising therefrom belongs to him; acknowledgment of which is made here.

1.7.

SYLVANUS G. MORLEY
Archaeology

YB 18:317, 320-321, 1919

During the month of March 1919, Mr. Morley visited Costa Rica and Nicaragua. The archaeological collections in the national museums at San José and Managua respectively, as well as the larger private collections, were examined, but beyond the ceramic remains no traces of direct Maya influence were found.

The decorative motives in pottery occasionally have elements which resemble the Maya ceramic designs, but as a whole the material cultures of the two countries, judging from the collections examined, show few such resemblances, and we may probably assume that, if felt at all, the Maya influence was but slight.

The Lenca, on the eastern Maya frontier [Chapter 1.4 this volume], and the Pipil, a Nahuatlan people along the southeastern frontier, formed a fairly effective linguistic barrier against a general southeastward extension of the Maya civilization, and although the material cultures of the Lenca and Pipil themselves show a strong Maya influence, particularly in their ceramic art, the original Maya strains had become greatly attenuated by the time such borrowings had been passed on to the tribes of Nicaragua and Costa Rica.

Two trips were made to the ruins of Copán, Honduras, one in December 1918, and the other in June 1919, to secure certain final data for a monograph on the inscriptions of that city (Morley 1920). During the course of the last visit, the mound of Stela 7, where the most archaic monuments at Copán have been found, was excavated, disclosing (among other things) a cruciform vault or chamber underneath the foundation-stone of Stela 7, but no new monuments.

Valuable information as to the original provenance of Stelae 15 and 7 and Altars L', M', T, and U was received from the three oldest inhabitants of the modern village, an aged trio between 70 and 80 years of age. The memory of these informants reaches back clearly to 1860; the oldest was an old lady of nearly 80, whose recollections extend to 1850. All three remember distinctly when the dense tropical forest, described by Stephens in 1839, still filled the entire valley, and when the modern village, now numbering a thousand souls, was composed of only three houses in small clearings in the forest. The information given by these people has proved of great help in checking up the original provenance of the six monuments mentioned.

Before leaving, Mr. Morley installed a small local museum in the cabildo, composed of the fragmentary monuments he has been collecting from the different houses and patios of the village during the past five years. The material left in the new museum comprises the following:

1. Stela 7, two large pieces.
2. Stela 15, two large pieces and one small piece.
3. Stela 22, one medium piece.
4. Stela 21, one small piece.
5. Stela 20, three pieces, one large, the other two medium.
6. Stela 24, one large piece.
7. Stela 25, two small pieces.

8. Fragment E', one small piece.
9. Fragment Y', one small piece.
10. Fragment Z', one small piece.
11. Altar S, complete in one piece.
- 12-24. Fragments V', 13 small pieces of archaic stela.

The discovery of the meaning of the "Winged Cauac" sign as a variant for the tun-sign, announced in [Chapter 1.5 this volume] is already fulfilling the anticipations there expressed as to its importance in the study of Maya chronology. By means of this sign, it has recently been possible to date a beautifully sculptured peccary skull taken from Tomb 1 at Copán by the First Peabody Museum Expedition in 1892, the inscription and date of which, although unusually well preserved, had long baffled decipherment. By the identification of this new variant for the tun-sign, it is now possible to date the text in question as 9.7.8.0.0, 1 Ahau 3 Ceh. This latter is the first contemporaneous date in the *Corpus Inscriptionum Mayarum* (Morley 1948) which has yet been found, that may be referred to the katun-ending in 9.8.0.0.0, and fills a previous lacuna in the chronological record at Copán. It is confidently anticipated that this glyph will prove of increasing value, particularly in the decipherment of New Empire texts.

1.8.

SYLVANUS G. MORLEY

Archaeology

YB 19:321-324, 1920

The first four months of 1920 were devoted to the completion of the monograph on *The Inscriptions at Copán* (Morley 1920) which appeared in April. As originally contemplated, this investigation was to have included a study of all the Maya inscriptions [Chapter 1.2 this volume], but soon after its inauguration it became apparent that the hieroglyphic texts at Copán alone, about 40 percent of the *Corpus Inscriptionum Mayarum* (Morley 1948), were sufficient to merit monographic treatment. Meanwhile the research has been broadening in other directions. Recent advances in the decipherment of previously unknown glyphs, the accumulation of a large amount of new material gathered by the Carnegie Institution's Central-American expeditions for 1915 to 1920 [Chapters 1.3-1.6 this volume], while delaying publication of the results,

have at the same time made possible a much more exhaustive presentation of the subject and the inclusion of much new related matter. As completed, this volume with its appendices presents a standard cross-section of Maya chronology to which all other ancient American cultures must ultimately be referred for their true positions in time.

During the final phases of this investigation Mr. Morley had the collaboration of Mr. William Gates, of Point Loma, California, and Dr. Carl E. Guthe, of Phillips Academy, Andover. Mr. Gates compiled the index, contributed a study of the distribution of the Maya linguistic stock (Appendix XII), and assisted in the preparation of the appendix on the correlation of Maya and Christian chronology (Appendix H), besides generously placing his large and important collection of manuscript material at the author's service. Dr. Guthe verified all the Maya calculations, as well as all the bibliographic references and citations, and spent the month of April in Washington on the final revision of the page proof.

The staff of the 1920 Central American expedition took the field at the end of April. The objectives of the party (composed of Mr. Morley and Dr. Guthe) were, first, the exploration of the northern part of the Department of Petén, Guatemala (into which no archaeological expeditions had penetrated for the past four years), for the purpose of ascertaining whether any new sites with associated hieroglyphic monuments had been discovered by chicle-bleeders during the period; second, a visit to the village of Copán, Honduras, to present to that municipality a specially bound copy of Publication 219 (Morley 1920).

The trip to Petén, although less than month in duration, was unusually successful. The expedition first visited the capital of the Department, the island village of Flores and placed itself in touch with the local authorities. No large sites had been discovered in the central part of Petén during the past 4 years, and the expedition returned to the frontiers of British Honduras, preparatory to making another trip into the northeastern corner of the department, which offers the most promising field for exploratory work. At Benque Viejo, British Honduras, information was received of a new site, about 60 miles [96.6 km] to the northwest, and a mule-train was engaged and the party proceeded thither during the last fortnight in May. The new site, to which the name Xultún was given, proved to be of great importance, no less in fact than a city of the second class with two principal plazas, 50 subsidiary courts, and 18 sculptured monuments. It has more structures, covering a larger area, than either Piedras Negras or Quiriguá, and has more sculptured monuments than either Nakúm or Palenque. It is larger than La Honradez in the same

region, and was probably the largest city of the Old Empire in northeastern Petén.

The inscribed monuments are the most important feature of the new city. They are found around the sides of the two principal plazas, 10 in Group A and 8 in Group B, all the earlier monuments being in the latter and all the later ones in the former. Of these 18 sculptured stelae (no plain stelae were found at the site), eight have Initial Series dates, two have Period-Ending dates, and eight are as yet indeterminate. Of the Initial Series stelae, the dates of three have been surely deciphered, and a fourth probably so, as follows:

Table 1.8.1. Calendrical Decipherments, Initial Series Dates, Xultún.

						Approx.
Group A	Stela 3	10.1.10.0.0	4 Ahau	13 Kankin		600 AD
Group A	Stela 10	10.3.0.0.0	1 Ahau	3 Yaxkin		630 AD
Group B	Stela 11	9.15.0.0.0	4 Ahau	13 Yax (?)		472 AD
Group B	Stela 13	9.14.0.0.0	6 Ahau	13 Muan		452 AD

Stela 10 is of unusual importance since it is the latest monument, by 20 years, yet reported from any Old Empire site. The date is recorded by an Initial Series, the coefficients of which are all bar and dot numerals, and there is no doubt as to the accuracy of the reading given. It is interesting to note that the discovery of this monument proves that the close of the Old Empire was contemporaneous with the beginning of the New Empire, as suggested in *The Inscriptions at Copán*, since the date on the Temple of the Initial Series at Chichén Itzá, in northern Yucatán (New Empire), is just 10 years earlier than the date of Stela 10 at Xultún¹ (Old Empire); in a word, the monumental series of the Old and New Empires are now seen to, have overlapped by at least 10 years. On the basis of the dates thus far deciphered, the city would seem to have had a period of occupation of about 180 years, being founded in the Middle Period of the Old Empire and occupied down to the close of the Great Period, possibly even being the last Old Empire city to be abandoned.

More than half of the Xultún stelae (11 out of the 18) have fallen with their sculptured faces down, so that they are probably in excellent state of preservation. The 1920 expedition, with the means at its disposal, was able to turn only two, of these, but the almost perfect condition of their relief and the beauty of the subjects portrayed (an elaborately costumed deity ruler, or priest, with accompanying inscription) justify the belief that when the expedition returns next year to turn over the others, an unusually fine group of sculptured panels will be recovered.

Before leaving Petén, notices in Spanish to the chicle-workers, to be on the lookout for new sites during their

Figure 1.8.1. Xultún, Great Plaza, (Group A) plan, showing location of principal temples (Roman numerals) and sculptured monuments (Arabic numerals).

Figure 1.8.2. a. Xultún, Stela 3, recording the date 10.1.10.0.0 of the Maya era, approximately 600 AD; b. Xultún, Stela 10, recording the date 10.3.0.0.0 approximately 630 AD.

excursions into the bush during the current rainy season, were extensively distributed in the frontier towns and chicle camps. Adequate rewards were offered for such information, and it is anticipated that other new sites will be located in the region as a result of this measure.

The second trip (to Copán, Honduras) also had satisfactory issue. Upon the arrival of the expedition at the village, the alcalde for the current year, Don Tobias Guerra, arranged for a special session of the cabildo, all the villagers being invited to attend. At this meeting *The Inscriptions at Copán* (Morley 1920) was formally presented to the municipality in the name of the Carnegie Institution of Washington and accepted by the village authorities. This ceremony was duly entered into the Book of the Acts of the cabildo of Copán, and a certified copy of the act was furnished for deposition in the archives of the Institution.

During the past five years Mr. Morley has made annual visits to Copán and the villagers have warmly cooperated in the Institution's investigations there. Equally friendly relations have been established with

the central authorities at Tegucigalpa, the capital, and the way paved for closer cooperation in the future.

The field season closed with a visit to Guatemala City, where arrangements were perfected with the Guatemalan government, through the Ministry of Foreign Relations, for continuing the archaeological exploration of Petén next season, and a permit was secured for excavating anywhere in the department, it being understood that all specimens recovered should remain in the republic. There exists a friendly and sympathetic interest in the Institution's activities in both Guatemala and Honduras (the southern Maya field), and the opportunity for intensive archaeological investigations in either of these countries was never so favorable as it is now.

NOTES

1. *Xul* is the Maya word for "end" or "close," and *tun* the word for stone. *Xultún*, therefore, may be translated "end stone" or "last stone," the name being suggested by the fact that the latest Old Empire monument yet reported is Stela 10 at this site.

1.9.

SYLVANUS G. MORLEY
Archaeology

YB 20:359–364, 1921

The Central American Expedition for 1921 sailed from New Orleans for Puerto Barrios, Guatemala, on January 7, remaining in the field for five months. The staff consisted of Dr. Morley, Dr. Carl E. Guthe, Mr. William Gates, Mr. O. G. Ricketson, Jr., and Mr. A. K. Rutherford.

Owing to this increase in personnel over that of former years, it was possible not only to cover more territory than in any previous season, but also to enlarge the field of investigation, thus adding excavation proper and a first-hand study of the Maya linguistic problem to the usual exploratory work of the Institution in this region.

The activities of the year may be classified and described under three headings as follows: 1. The further exploration of northern Petén in search of archaeological sites and hieroglyphic inscriptions by Dr. Morley (6th season); 2. The excavation of Tayasal, the last independent Maya capital, on an island in the lake of Petén Itzá in northern central Petén by Dr. Guthe (new); and, 3. A study of the Maya dialects spoken at the present time in northern British Honduras and in the Department of El Quiché in the highlands of Guatemala by Mr. Gates (new).

After a preliminary trip to Guatemala City to notify the Ministry of Foreign Relations that the Carnegie Institution was prepared to begin operations under the permit granted to it in June 1920 by the Government of Guatemala for exploration and excavation in the Department of Petén [Chapter 1.8 this volume], Dr. Morley returned to Belize, where he was met by Messrs. Ricketson and Rutherford, and thence proceeded by motor-boat up the Belize River to El Cayo on the frontier of British Honduras, where a mule-train was secured for the journey into the interior of Petén.

The exploratory work of the year was divided into three trips: The first from February 7 to March 6 in northeastern Petén to the ruins of Xultún, Uaxactún, and Nakúm; the second from March 23 to April 11, in northern central Petén, to the ruins of Benque Viejo, Naranjo, El Encanto, Tikal, Uolantún (new), Ixlú (new), and Tayasal, and the third from April 22 to June 1 in northwestern Petén to the ruins of Itsimté and Piedras Negras.

The new material discovered during these three trips may be briefly summarized as follows: 1. Two new sites, Uolantún,¹ 4 miles [6.5 km] south of Tikal in northern central Petén, and Ixlú² at the western end of

Lake Petén Itzá; 2. Seventeen new Initial Series; 3. Twenty-one new monuments³; and, 4. Thirty newly deciphered dates⁴

The 17 new Initial Series are [outlined in Table 1.9.1].

Table 1.9.1. Calendrical Decipherments, Xultún, Naranjo, Tikal, Uolantún, and Piedras Negras.

Site	Monument	Maya Date	Christian Era
Xultún	Stela 5	9.12.0.0.0	413 AD
Xultún	Stela 6	9.3.7.0.0	242 AD
Xultún	Stela 11	9.5.7.0.0	282 AD
Xultún	Stela 21	9.14.10.0.0	462 AD
Naranjo	Stela 25	9.5.18.4.0	100 BC
Tikal	Stela 6	9.4.0.0.0	255 AD
Tikal	Stela 15	9.3.0.0.0	235 AD
Uolantún	Stela 1	8.18.13.5.11	150 AD
Piedras Negras	Stela 23	9.16.10.0.0	502 AD
Piedras Negras	Stela 26	9.9.15.0.0	368 AD
Piedras Negras	Stela 30	9.5.0.0.0	275 AD
Piedras Negras	Stela 32	9.10.15.0.0	388 AD
Piedras Negras	Stela 34	9.10.19.5.9	392 AD
Piedras Negras	Stela 38	9.12.10.0.0	423 AD
Piedras Negras	Stela 39	9.12.5.0.0	418 AD
Piedras Negras	Stela 40	9.15.14.9.13	486 AD

Note: Stela 23 has two Initial Series, but one is entirely destroyed except for the Initial Series introducing glyph.

Perhaps the most important discovery of the field season was the decipherment of the Initial Series on Stela 25 at Naranjo as 8.5.18.4.0, which makes it the earliest historical Initial Series yet reported anywhere. This early Baktun 8 date, although it does not represent the contemporaneous date of this monument, nevertheless antedates the Initial Series on the Tuxtla Statuette (8.6.2.4.17) by 4 years and that on page 70 of the Dresden Codex (8.6.16.12.17) by 18 years, the two earliest historical Initial Series previously known.

The outstanding importance of this discovery lies in the fact that we may probably interpret it as indicating that the Maya in Baktun 9 still preserved definite traditional knowledge, if not indeed actual contemporaneous historical records, reaching back to the beginning of Baktun 8, 4 or 5 centuries earlier.

Of scarcely less importance were the discovery and decipherment of another Baktun 8 Initial Series at Uolantún. In the case of this monument, however, its Initial Series (8.18.13.5.11) is the contemporaneous date, which makes it the second oldest Maya monument yet reported, being 81 years later than Stela 9 at Uaxactún and 66 years earlier than the earliest date yet deciphered at Tikal (9.2.0.0.0 on Stela 9).

Uaxactún, containing the oldest Maya monument yet reported (8.14.10.13.15, on Stela 9), is 10 miles [16.1 km] north of Tikal [Chapter 1.4 this volume] and Uolantún is 4 miles [6.5 km] south.

Figure 1.9.1. Naranjo, Stela 25. a. The inscription on this monument opens, with the date 8.5.18.4.0 (100 BC) the earliest historical Maya date yet discovered. The contemporaneous date, however was 445 years later or 345 AD; b. Stela 1 at Uolantún. This monument bears the date of 8.18.13.5.11 (150 AD) which makes it the next oldest Maya yet discovered, Stela 9 at Uaxactún antedating it by 80 years. It has been broken into fragments in ancient times and the top fragment was reshaped for use as an altar after it had been broken.

In the same vicinity, at El Encanto, 12 miles [19.3 km] northeast of Tikal, Dr. R. E. Merwin discovered another early monument in 1910 (Tozzer 1913:152, 163, 194); and although it has been impossible to decipher the date of this, on stylistic grounds it may surely be referred to the early part of Baktun 9.

At Tikal four very early Baktun 9 dates were deciphered this season as follows:

Table 1.9.2. Calendrical Decipherments, Baktun 9 Dates, Tikal.

Tikal	Stela 9	9.2.0.0.0	216 AD
Tikal	Stela 7	9.3.0.0.0	235 AD
Tikal	Stela 15	9.3.0.0.0	235 AD
Tikal	Stela 6	9.4.0.0.0	255 AD

Indeed there are only four other undated monuments now known at this site which on stylistic grounds may be earlier: Stelae 1, 2, 4 and 18. This clustering of the earliest Old Empire monuments, either at or around Tikal, strongly suggests that this was the first part of the Petén region to be occupied by the Maya when they migrated thither from some habitat farther to the west, possibly somewhere along the Gulf Coast

of Mexico (For hypotheses concerning the origin of the Maya civilization see Morley 1920:402–415).

These several cities are located at the head of the Holmul Valley, and although much further exploration throughout Petén will be necessary before final conclusions can be drawn, indications now are that the upper reaches of this valley may have been the center of the earliest Maya occupation in the Old Empire region.

Somewhat surprising was the decipherment of two early dates at Xultún, the large city of the second class discovered by the Carnegie Central American Expedition of 1920 [Chapter 1.8 this volume]. That this was a comparatively recent Old Empire site seemed to be indicated by the very late dates deciphered there last year, 10.1.10.0.0 on Stela 3 and 10.3.0.0.0 on Stela 10; also by the failure to find any date earlier than the close of the Middle Period (9.14.0.0.0 on Stela 15),⁷ and more particularly by the location of this city, well up in the northeastern corner of Petén directly in the line of migration followed by the Maya northward into Yucatán at the close of the Old Empire.

However, the decipherment of the dates of Stelae 6 and 11, 9.3.7.0.0 and 9.5.7.0.0. respectively, carries the monumental sequence here back toward the beginning of Baktun 9 and gives a recorded occupation of this site of nearly a baktun (9.3.7.0.0 to 10.3.0.0.0), that is, for 387 years. The discovery of these two early dates at Xultún indicates that the Maya spread northeastward from around Tikal for a considerable distance at a fairly early date and established themselves in northeastern Petén not very long after they had colonized the Copán region, 200 miles [322 km] to the southeast.

The new site at the eastern end of Lake Petén Itzá, Ixlú, contains five new monuments, viz, two sculptured stelae, a sculptured altar, and two plain stelae. The first three date from the very close of the Old Empire, Stela 1 from 10.1.10.0.0 and Stela 2 and the altar from 10.2.10.0.0, and it is obvious that this is a very late site. These two dates exactly alternate by lahuntun intervals (3,600-day periods) with the two stelae found in the modern village of Flores on an island at the extreme western end of the lake, viz:

1.9.3. Calendrical Decipherments, Stelae, Flores and Ixlú.

Flores	Stela 1	10.1.0.0.0	590 AD
Ixlú	Stela 1	10.1.10.0.0	600 AD
Flores	Stela 2	10.2.0.0.0	610 AD
Ixlú	Stela 2	10.2.10.0.0	620 AD

These new monuments are magnificent specimens of Old Empire sculpture; indeed, Stela 2 and its associated altar will rank among the very finest examples of Maya plastic art that have come down to us.

Dr. Guthe's discovery of two inscribed monuments at Tayasal, the last Itzá capital (1450–1697 AD), was a find of first importance. One is a stela, the other a lintel. Unfortunately, only the base of the former is preserved; enough remains, however, to show that it had been inscribed with a double column of glyphs on the back.

The lintel, although broken, is more nearly complete. It clearly records a Calendar Round date, of which the day is surely 11 Ahau and the month 18?, the incomplete month-sign bearing more resemblance to Mac than to any other month sign. There were no katuns, lahuntuns, or hotuns which ended on the day 11 Ahau 18 Mac during the occupation of Tayasal, but the tun ending 12.5.9.0.0 (1467 AD) fell on this date. If the above reading is correct, this lintel must have been carved very shortly after the Itzá established themselves at Tayasal; unfortunately, the doubtful identity of the month sign casts a cloud on its accuracy. In any event, Dr. Guthe's discovery of inscribed monuments at the very beginning of his work justifies the expectation that subsequent excavations will uncover other similar material and shed much light on this final phase of independent Maya history.

The last fortnight of the field season (May 18 to June 1) was spent at Piedras Negras on the Usumacinta River in the westernmost corner of Petén. As already noted, five new monuments and nine new Initial Series were discovered at this site. Scale drawings of all Initial and Supplementary Series were made and a large number of photographs were secured.

The most important contribution here was the filling in of lacunae in the sequence of the hotun markers, so that now the corresponding marker for every 1,800-day period from 9.10.5.0.0 to 9.18.5.0.0, 33 in all, has been identified. In some cases, as for example, Stelae 39, 38, and 40, it was even possible to predict what their corresponding dates would be in advance of the actual decipherment of them, because these particular hotun-endings, 9.12.5.0.0, 9.12.10.0.0, and 9.15.15.0.0, respectively had not been represented heretofore in the monumental sequence. These three new monuments were found to record, precisely these three dates.

Piedras Negras presents a longer unbroken sequence of hotun markers than any other Maya city, 33 (165-years), as compared with 14 (60 years) at Quiriguá, the next most perfect. This feature, it is anticipated, will greatly assist in the final elucidation of the Supplementary Series, which is a lunar count associated in some as yet undetermined way with eclipse phenomena.

One other discovery at Piedras Negras is worthy of special namely, the finding of a fragment of Stela 30, reused in the roofing of a drain through the platform

north of Mound VI. This indicates that Stela 30 had been broken in ancient times, since a piece of it had been built into the roof of a drain before the city had been abandoned. Owing to this sheltered position, its inscription was perfectly preserved and records the date 9.5.0.0.0 (275 AD). This date is 75 years older than the earliest date previously reported at this site (9.8.15.0.0 on Stela 25) and carries the foundation of this city at least as far back as the first quarter of Baktun 9.

This pushing back of the monumental remains to the early part of Baktun 9, and even earlier, at a number of sites, Tikal, Xultún, Uolantún, and Piedras Negras, for example, is one of the most significant results of the last field season, and it is confidently anticipated that further exploration, especially in the region around Tikal, will shed much light on the beginnings of the Maya civilization in the Old Empire region.

NOTES

1. This Maya word means *uolan*, something which has been rounded, *tun*, stone, *uolantun*, stone which has been rounded. This site was so named because of a unique feature presented by the single monument found there. This monument had been broken in ancient times and the top fragment, a piece 2.5 feet [76 cm] long, had been reshaped to serve as a round altar for the larger bottom piece, hence the name stone which has been rounded.

2. *Ixlú* is the Maya word for a certain fish found in Lake Petén Itzá, after which the arroyo running into the eastern end of the lake is named. As this second site is just north of the north bank of the Ixlú Arroyo it has been given the same name.

3. This total includes the two new monuments (a stela and a lintel) found by Dr. Guthe early in April at Tayasal.

4. This total includes 18 new Period Ending dates, and 12 out of the 17 new Initial Series, the remaining five new Initial Series not having been surely deciphered as yet.

5. Mr. Gates has suggested this word for the 144,000-day period, heretofore known as the cycle. It is composed of the Maya word *bak*, meaning 400 (Beltrán de Santa Rosa 1859:201), and *tun*, the word for the 360-day period. An analogue for this exists in the word for the 7,200-day period, *katun*, generally assumed to be a contraction for *kaltun*, *kal* being the word for 20. The word *hotun*, which has been suggested for the 1,800-day period, is derived in the same way, *ho* being the Maya for 5, and hotun five times the tun or the 1,800-day period.

6. The contemporaneous date of Stela 25 at Naranjo is 9.9.0.0.0, 445 years later than the date of its Initial Series, which is still 20 years earlier than the earliest contemporaneous date previously reported at this site, that is, 9.10.0.0.0 on the reused lintel found in the Hieroglyphic Stairway.

7. In the first announcement of the discovery of this site this monument was called Stela 13. In the revised nomenclature it has been assigned the number 15.

1.10.

SYLVANUS G. MORLEY

Archaeology

YB 21:310–318, 1922

The members of the Central American Expedition for 1922 were Messrs. Morley, Guthe, Lothrop, Ricketson, Jessup, and Sopeña; Messrs. Cook, Loomis, and Martin, of the Bureau of Plant Industry, United States Department of Agriculture, also accompanied the party on the first trip into Petén during the last half of March and early April.

Owing to the increasing personnel of the Central American expedition and to the extension of its activities, it has become impracticable for all members to take the field at the same time. Dr. Morley and Dr. Lothrop sailed from New Orleans for Puerto Barrios, Guatemala, on January 14; Dr. Guthe and Messrs. Ricketson, Jessup, and Sopeña sailed from New Orleans for Belize, British Honduras, on January 28; and Messrs. Cook, Loomis, and Martin for the same destination on February 25.

The activities of the current field-season may be described under four main headings, as follows: 1. A further exploration of the east coast of Yucatán, notably of the ruins of Tulum, by Dr. Morley and Dr. Lothrop (third season); 2. A continuation of Dr. Morley's explorations in northern Petén in search of new archaeological sites and hieroglyphic inscriptions (sixth season); 3. An investigation of the agricultural possibilities of the northern Petén region by Mr. O. F. Cook; and, 4. A continuation of Dr. Guthe's excavations at Tayasal, the last Maya stronghold on the shores of Lake Petén Itzá (second season).

After the usual preliminary trip to Guatemala City, to arrange for the continuation of the Institution's investigations in the Department of Petén under the permit granted by the Government of Guatemala in June 1920, Dr. Morley and Dr. Lothrop returned to Belize, where they were met by Messrs. Ricketson and Sopeña. A small schooner, with auxiliary gasoline engine, the *Esperanza*, was chartered and on February 7 the expedition sailed for the ruins of Tulum on the east coast of Yucatán, Mexico. A stop was first made at Payo Obispo, Quintana Roo, to secure the necessary permits from the local authorities, and here Señor Miguel Carral joined the party as the official representative of the Ministry of Fomento.

This trip lasted from February 7 to March 6, during which time two new sites, Tancar and Xelhá¹ were discovered, mapped, photographed, and described, and a more extensive study was undertaken at the ruins of Tulum.

At Tancar, 4 miles [6.5 km] north of Tulum and 0.25 mile [0.4 km] back from the beach, there are two principal plazas and about a dozen stone buildings. At the southern end of the site is a cave with rock carvings, a roughly carved, stone slab leaning against the back wall, and a small square altar of stone and stucco.

Xelhá lies some 15 miles [24.2 km] north of Tulum and a mile [1.6 km] inland from the sea. The lagoon of the same name extends perhaps half a mile [0.8 km] back from the sea, and bifurcates at its inner end. The point of land lying between these two reaches of the lagoon has a narrow neck, where it joins the mainland and this had been fortified by a well-laid stone wall, 150 feet [45.7 m] long, 25 feet [7.6 m] thick, and 10 to 12 feet [3.1–3.7 m] high, pierced by a single offset passageway, the whole construction constituting an admirable defense against an attack by land. Half a mile [0.8 km] back from the end of this lagoon lies the main group of ruins, centering around a single plaza 315 feet [96 m] long by 75 feet [22.9 m] wide. There are 10–12 stone buildings, the principal temple being in an excellent state of preservation, with the original sapote beams of the door-lintel still in position.

A fortnight was spent at the ruins of Tulum, easily the largest site on the east coast of Yucatán, where sufficient data were collected to complete the material for a preliminary report, Dr. Morley first visited this site in 1913, again with Dr. Gann and Dr. Lothrop in 1916 [Chapter 1.5 this volume] and with Dr. Gann and Mr. Held in 1918 [Chapter 1.6 this volume].

This year a much more extensive investigation was possible. The forest was felled completely inside the inner enclosure and around all the principal, temples. Dr. Lothrop, made a number of tracings of the mural paintings, especially in Temple 16, as well as extensive architectural and stylistic notes. Mr. Ricketson, assisted by Mr. Alfred Harvey, resurveyed the city, correcting and amending the map made by Dr. Morley and Dr. Lothrop in 1916. Individual plans and elevations of all constructions within the great wall were also made, and more than 200 photographs were secured by Mr. Sopeña.

The most important contributions made this year at Tulum were:

1. The discovery that the principal temples of the city, save only these within the inner enclosure (the Castillo Group) and the so-called Guard House by the East Gate of the North Wall, are distributed along a single main thoroughfare running the entire length of the city from the West Gate in the North Wall to the West Gate in the South Wall. This is unique feature in the assemblage of Maya structures, the regular practice being arrangement around a single plaza, or groups of connected plazas.

2. The discovery of three new stelae, two of which are carved, the third being covered with stucco and then painted a brilliant light blue. Stelae 2 and 3 (carved) are very similar stylistically to the late stelae at Mayapán, notably to Stelae 8 and 9 (Morley 1920:574–575; [Chapter 1.6 this volume]). All four of these stelae are surrounded with borders of the same kind, that is, squares with central dots; and Stela 2 at Tulúm, like Stela 9 at Mayapán, has an ahau sign as the only glyph upon it. The best decipherment indicates that this monument dates from some Katun 2 Ahau. Any given katun-ending recurred every 256 years, though on stylistic grounds only the last three occurrences of this katun need be considered here: 1004 AD, 1261 AD, and 1517 AD. Of these, the last (1517) appears most probable to Dr. Morley, although the second (1261) is by no means an unlikely date for this stela. The first (1004) is almost certainly too early. Only one piece of Stela 3, the top, was recovered; this was built into the western pier of Structure 33 (a small altar) in ancient times.

All of the archaeological evidence the architecture, the mural paintings, the stucco ornamentations, the serpent columns, the Mayapán type of stelae, everything, indeed, save only the comparatively early Stela 1 (10.6.10.0.0.?, approximately 699 A.D.) points to Tulúm, as having reached its zenith after 1400 A.D., and it should not be forgotten that it was occupied as late as 1518, when Juan de Grijalva made the first voyage down the east coast of Yucatán (Ternaux Compans 1838:11).

On March 13 the expedition again left Belize by motor-boat for El Cayo, at the head of navigation on the Belize River, and on March 18 set out from El Cayo for northern Petén with a pack-train of 42 mules and horses. The personnel on this trip consisted of Dr. Morley and Dr. Lothrop, Messrs. Ricketson, Sopeña, and Harvey, Messrs. Cook, Loomis, and Martin of the United States Department of Agriculture, and Mr. A. M. Adams, whose services as transport manager had been placed at the disposition of the expedition by Mr. James Craik, of Belize, the local manager of the Chiclé Development Company.²

This trip lasted a month, during which the ruins of Naranjo, Nakúm, Uaxactún, Tikal, Uolantún, Tayasal, Ixlú, and Chichantún³ (a new site of Class 4), were visited, the party returning to El Cayo on April 11.

On April 14, Messrs. Ricketson and Harvey revisited the ruins of Naranjo, where they made a surveyed map of that site, returning to El Cayo again and thence to Belize early in May. The only previous map of Naranjo had been that made in 1904, by its discoverer, Mr. Teobert Maler, which was inaccurate and incomplete. The new map shows Naranjo as considerably larger than appears from Maler's map, indeed, when

considered with its 36 sculptured stelae and its Hieroglyphic Stairway, it may well be regarded as one of the largest cities of the Old Empire.

On April 18, Dr. Morley and Mr. Sopeña left El Cayo for a month's trip across the northeastern corner of the Department of Petén, penetrating to within 5 miles [8.1 km] of the Mexican boundary at a point almost due north of Flores. Two new sites were discovered: Xmakabatún⁴ (a city of Class 3) with four sculptured stelae and seven plain ones, and Naachtún.⁵ This name was given to the now Class 2 site found this year because of its extreme remoteness, being at the very center of the Yucatán peninsula, far removed from every point of approach] (a city of Class 2) with 11 sculptured Stelae and seven plain ones; the party returned to El Cayo on May 14 and to Belize on May 18.

The new material discovered during the course of these several trips in northeastern Petén may be briefly summarized as follows: 1. Three new sites: Naachtún, 5 miles [8.1 km] south of the northern boundary of Petén and almost due north of Flores; Xmakabatún, 35 miles [56.4 km] north of El Cayo and just west of the eastern boundary of Petén; Chichantún, at El Gallo, on the camino real from Plancha de Piedra to Flores, eastern central Petén; 2. Fourteen new Initial Series; 3. Thirty-one new monuments; and 4. Nineteen newly deciphered dates, including all, but one of the Initial Series under no. 2.

The 14 new Initial Series are [listed in Table 1.10.1].

Table 1.10.1. Calendrical Decipherments, Initial Series Dates, Naachtún, Quiriguá, and El Encanto.

<i>Site</i>	<i>Monument</i>	<i>Maya Date</i>	<i>Christian Era</i>
Uaxactún	Stela 18	8.16. 0.0.0	97 A.D.
Uaxactún	Stela 19	8.16. 0.0.0	97 A.D.
Naachtún	Stela 1	9. 9.10.0.0	364 A.D.
Naachtún	Stela 2	9.10.10.0.0	383 A.D.
Naachtún	Stela 3	9. 5. 0.0.0	275 A.D.
Naachtún	Stela 4	Undeciphered	
Naachtún	Stela 6	9. 6.10.0.0	304 A.D.
Naachtún	Stela 7	9.17. 0.0.0	511 A.D.
Naachtún	Stela 8	9.16. 0.0.0	492 A.D.
Naachtún	Stela 9	9.15. 0.0.0	472 A.D.
Naachtún	Stela 10	9.16.10.0.0	502 A.D.
Quiriguá	Stela T	0.14. ?.?.?	452 A.D.
Quiriguá	Stela U	9. 2. ?.8.0	216–235 A.D.
El Encanto	Stela 1	9. 8. ?.9.?	334–354 A.D.

The most important results of Dr. Morley's explorations this season, center around the highly significant new stela found at Uaxactún, and the discovery of so large a new city as Naachtún. The ruins of Uaxactún were discovered in 1916 by the Institution's Central American Expedition. At that time this site was unique in having the first and only Baktun 8 Initial

Series monument then known, namely, Stela 9, recording the date 8.14.10.13.15, approximately 68 A.D. [Chapter 1.4 this volume]. Last year another Baktun 8 Initial Series monument was, discovered at a new site, Uolantún, 12 miles [19.3 km] south of Uaxactún, recording the date 8.18.13.5.11, approximately 150 A.D. [Chapter 1.9 this volume].

This year no less than four more Baktun 8 dates were deciphered at Uaxactún, three of them on new monuments: Stelae 14, 18, and 19, and the fourth on Stela 4, discovered in 1916 (Table 1.10.2).

Table 1.10.2. Calendrical Decipherments, Stelae, Uaxactún.

Site	Monument	Maya Date	Christian Era
Uaxactún	Stela 18	8.16.0.0.0	97 AD
Uaxactún	Stela 19	8.16.0.0.0	97 AD
Uaxactún	Stela 4	8.18.0.0.0	137 AD
Uaxactún	Stela 17	8.19.0.0.0	157 AD

The first two, Stelae 18 and 19, stand in front of the same temple and record exactly the same day, an Initial Series in each case, the coefficients being expressed by simple bar and dot numerals, and their decipherment is correspondingly certain. This date is less than 29 years later than the date on Stela 9 at this site, and these two stelae, therefore, become the second and third earliest monuments yet found in the Maya area. They also corroborate the reading suggested for Stela 9 six years ago. Although the dates on Stelae 4 and 17 are recorded as Period Endings, both are reasonably certain, particularly that on Stela 4, which shows quite clearly 8 Zotz followed by an Ending-sign. This can hardly be other than 8.18.0.0.0 12 Ahau 8 Zotz, as suggested above.

Another important new early monument discovered at Uaxactún this year is Stela 20, probably dating from 9.3.0.0.0 (235 A.D.), also recorded as a Period Ending. The front is carved with an heroic-sized human figure, front view, carrying a ceremonial bar in the arms, the presentation being almost identical with that on Stela 7 at Copán, for example, so close, in fact, that the sculptors of these two widely separated monuments must have had a common source of inspiration, a striking example of the homogeneity of Old Empire culture even at this early date.

Another important monument found this year was the fragment of a very early stela which had been worked down into a round altar in ancient times and re-used as such with Stela 9. Unfortunately, it was impossible to date this fragment exactly, but stylistically it would seem to have been at least as early as Stela 9, itself the earliest Maya stela known, if not indeed earlier.

The number of these early stelae at Uaxactún, coupled with the fact that the next earliest stelae elsewhere is nearly a century and a half later (Stela 9 at Tikal, 9.2.0.0.0, 216 A.D.),⁶ strongly indicates the advisability of further intensive investigation, including excavation at this site. No other site now known would probably shed more light upon the beginnings of the Old Empire (certainly so far as the Petén region is concerned) than Uaxactún, where all the earliest surely deciphered monuments have been found.

The geographic location of this site is also significant. It became apparent from this year's explorations that Uaxactún is located at the head of the Ixcán Valley⁷ in that mountain cluster which is precisely the very backbone of the Yucatán peninsula, the waters of the Ixcán River finding their way out through the Hondo River into Chetumal Bay and thence into the Caribbean Sea, on the east side of the peninsula. Northwest of Uaxactún 8 or 10 miles [4.9–16.1 km] is the

Figure 1.10.1. Uaxactún, Stela 19 (a) and Stela 18 (b). These two stelae record the same date: 8.16.0.0.0, approx. 150 A.D. Next to Stela 9 at this same site they are the two earliest Maya monuments known.

main divide of the peninsula, streams rising on the far side of this range, such as the Paixban River for example, flow out through the San Pedro Martír and San Pedro Candelaria Rivers into the Gulf of Mexico, while to the south are ranges beyond which lies the great interior drainage basin of which Lake Petén Itzá is the largest member.

Uaxactún is thus located at the geographical as well as the topographical center of the Old Empire region, the central point from which distribution subsequently took place to other regions, judging from the pronounced chronological priority of the Uaxactún dates.

Another factor contributing to the scientific importance of this site is its length of occupation (561 years), more than a century and a half longer than any other Old Empire city on the basis of the dated remains.

During the present field season two very late Old Empire monuments were also found here, their dates being recorded as Period Endings (Table 1.10.3).

Table 1.10.3. Calendrical Decipherments, Stelae, Uaxactún.

Uaxactún	Stela 13	10.0.0.0.0	571 AD
Uaxactún	Stela 12	10.3.0.0.0	630 AD

The former is the first monument yet discovered, dating from the closing day of Baktun 10. The previous katun-ending, 9.19.0.0.0, had been found recorded on four monuments at three different sites, as, for example, here at Uaxactún on Stela 7, at Naranjo on Stela 7 and 10, and at Quiriguá on Temple 1; and the succeeding katun-ending, 10.1.0.0.0, appears on eight monuments at five different sites: Benque Viejo, Stela 1; Flores, Stela 2; Ucanal, Stela 3; Nakúm, Stela D; and Seibal, Stelae 8, 9, 10 and 11, but no monument had been found previously dating from 10.0.0.0.0 until the discovery of Stela 18 at Uaxactún in April of this year.

The other Baktun 10 monument found this season (Stela 12) is of even greater importance. This records the date 10.3.0.0.0, which make it of exactly the same, age as Stela 10 at Xultún, discovered by the expedition of 1920 [Chapter 1.8 this volume], and together they have the unique distinction of being the two latest Old Empire monuments known anywhere.

Priority of origin, length of occupation, lateness of abandonment, centrality of location, all combine to make Uaxactún the most promising of all Old Empire sites for intensive operations.

Naachtún, the large new site discovered on May 3 of this year, is interesting chiefly because of its location, being the northernmost city of the Old Empire yet reported. It is on a low bench of hills toward the head and on the southern side of the Paixban Valley, the streams of which flow into the San Pedro Candelaria

River; it thus lies northwest of the ranges forming the main watershed of the Yucatán peninsula. The long axis of the city extends for about half a mile [0.8 km] east and west; there are two principal plazas and a score or more of subsidiary ones. The buildings are now mostly fallen, destroyed by the luxuriant forest growth, though here and there a wall is standing, mute witness to former magnificence.

An analysis of its inscriptions shows Naachtún was not as old as Uaxactún by more than two centuries, nor survived it as late by more than a century. Its art and architecture, in spite of its size, are provincial, probably because it was a frontier city, and its sculptures are not to be compared with those of Piedras Negras and Quiriguá, though both the latter sites have fewer structures and cover less area. The earliest date deciphered is 9.5.0.0.0 (275 A.D.) on Stela 3, and the latest, some time during Katun 17 (511–531 A.D.) on Stela 7. Judging by the provenance of the dated monuments, the Eastern Plaza was built during the Early Period and the Western Plaza during the Great Period, with no monuments thus far found dating from the Middle Period.⁸ Naachtún is an excellent example of a large provincial Old Empire city of mediocre esthetic achievement.

A few scattering new inscriptions should be noted here. Mr. R. D. Martin, of the U. S. Department of Agriculture, discovered a new monument at Naranjo, to which the name Stela 36 was given. This bears the Calendar Round date 12 Ahau 8 Pax, which corresponds to the Initial Series 9.17.10.0.0. (521 A.D.). There is a band of four glyphs across the top of the stela, the rest of the front, the back, and sides being plain. It would almost appear as though this monument had been left in an unfinished state.

At the conclusion of his explorations in Petén in May, before returning to the United States, Dr. Morley spent two days at Quiriguá, Guatemala, where two new stelae had been found on the summit of a hill 2 miles [3.2 km] west of the principal group.

These monuments, which were named Stelae T and U respectively, proved of exceptional interest, and one of them, Stela U, offers several perplexing problems. It has only four period-glyphs between the Initial Series introducing-glyph and the day-sign, and it is therefore evident that one of the period-glyphs has been omitted, probably the kin-sign.⁹ The best reading for the Initial Series is 9.2.?8.0, which in itself raises another problem. If Stela U really dates from Katun 2 as this reading would indicate, it would make it more than two and a half centuries earlier than the next earliest monument here at Quiriguá, an improbable situation. On the other hand, there are no Secondary Series on the monument to bring it down to the period of the other Quiriguá stelae.

The other new Quiriguá monument, Stela T, dates from some time in Katun 14, and because of its close stylistic similarities with Stela U, it seems not improbable that this latter monument also dates from the same katun, though this fact has not yet been established from its inscription.

Mr. O. F. Cook's study of the agricultural possibilities of the Petén region developed nothing in the way of the former use of agricultural terraces like those he found in Peru or in the Cahabón District of southern Guatemala, nor do the natural conditions indicate that the land was kept in permanent cultivation.

In a preliminary announcement Mr. Cook states:

The milpa system of agriculture, the planting of maize and other crops in temporary clearings, probably was used by the ancient inhabitants of Petén, as it still is by the modern representatives of the Mayas in the neighboring regions of Central America. The milpa system has a natural limit when the land becomes occupied by grasses, since, the burning over of grasslands does not kill the roots or allow crops to be planted. In the absence of plows or metal tools for the tillage of grass lands, primitive people generally were limited to the destructive, bush burning, milpa agriculture. But in view of the long occupation of the ancient sites in Petén, it is believed that precautions must have been taken to keep the milpa fires from spreading to adjacent lands, a custom still followed in the Cahabón district, south of Petén. By confining the fires to the milpas the fallow lands are kept in bush, and the complete deforestation and reduction of the country to a grass land, or savannah, are deferred. Nevertheless, a gradual extension of savannahs is to be expected in any populous region that is farmed continuously by the milpa system, so that in time the planting of corn or other crops is restricted and the population declines or moves to new lands, as the Mayas appear to have done when the cities of Petén were abandoned and new cities were built in Yucatán, in the sixth century A.D. (*The Official Record*, US Department of Agriculture 1(20):1, 3, 1922).

Extensive artificial terracing has been found recently in the hill country of western British Honduras, in the Cayo District, south of the Belize River: All the archaeological evidence here, however, pottery, mounds, etc., indicates that the region was occupied very much later than the lowlands of Petén, just west of it; that whereas the cities of the latter date from the Old Empire (down to 630 A.D.), the sites of the Cayo District are probably to be assigned to the very close of the new Empire, possibly as late as the fifteenth and sixteenth centuries.

It is suggested that this region may have been colonized from the highlands of Guatemala by groups of the southern Maya, the Kekchí, for example, who still

have villages as far north as San Antonio in southwestern British Honduras and San Luis and Poctún in southeastern Petén. The southern Maya probably developed the use of agricultural terraces after the abandonment of the Petén region and their migration southward into the mountain valleys of Guatemala (after 630 A.D.), so that the discovery of such terraces in the Cayo District may point to their southern origin, and thus corroborates rather than vitiates Mr. Cook's conclusions as to their non-existence during the Old Empire in Petén.

Further study of these terraces as well as of the archaeology of the Cayo District will be necessary before final conclusions may be formulated, but it already seems fairly evident that its occupation dates from a time long subsequent to the Old Empire period, and that its colonization possibly may not have taken place until after the thirteenth century.

On August 5, Dr. Morley sailed for Río de Janeiro, where he represented the Institution at the Twentieth International Congress of Americanists, held there August 20–30.

Dr. Guthe resigned from the Institution on August 1 to accept a position with the University of Michigan.

NOTES

1. Both of these names are probably of ancient origin. John Lloyd Stephens (1843) speaks of Tancar as early as 1841 and Oviedo mentions a point on the east coast of the peninsula named Xelhá three centuries earlier.

2. The president of this corporation, Mr. M. D. Bromberg of New York, has taken an active interest in Dr. Morley's investigations in Petén, offering all the facilities of the company's large field organization, camps, supplies, mule-trains, and credits, thus contributing largely to the successful exploration of this remote region.

3. Chichantún: small stone; *chichan*, small, and *tun*, stone. This name was given to this new Class 4 site because the two sculptured stelae found here were very small, not more than 4 feet [1.2 m] high.

4. Xmakabatún, stone without a name; *xmakaba*, without a name and *tun*, stone. This name was given to this new Class 3 site because of the fact that two of its four sculptured monuments (Stelae 3 and 4) had no hieroglyphs at all inscribed upon them, and the other two (Stelae 1 and 2) showed only the faintest traces of them.

5. Naachtún, distant stone; *naach*, distant or far off; and *tun*, stone.

6. Uolantún is an exception to this statement, but it is so small, having only a single pyramid and a, single monument, that it has been disregarded in this connection.

7. In Dr. Morley's report for last year it is stated that Uaxactún lies at the head of the Holmul Valley [Chapter 1.9 this volume]. Closer exploration this year established the fact that this site lies just north of the low divide between the Ixcán and Holmul Valleys, and that it is therefore at the head of the Ixcán valley instead.

8. Stela 2 really dates from the first decade of the Middle Period (9.10.10.0.0), but from its provenance it is evident that it was associated with an Early Period building.

9. The day-sign of the Initial Series terminal date is surely Ahau, indicating that the kin coefficient was zero, and as such could therefore be omitted without sacrifice of clarity (Morley 1914:127, 128; 1920:203, 301).

1.11.

SYLVANUS G. MORLEY

Archaeology

YB 22:267–272, 1923

Three separate and independent, expeditions were maintained in the field during the season of 1923, as follows: Dr. Morley in Mexico, Yucatán, Guatemala, and Honduras; Messrs. Ricketson and Love (Department of Terrestrial Magnetism, Carnegie Institution of Washington) in northeastern Petén; Guatemala; and Mr. Kilmartin (United States Geological Survey) at Tayasal on Lake Petén, Guatemala.

The activities in Middle American Archaeological Research for the current year may be described under five main headings, as follows: 1. The securing of permits from the Governments of Guatemala and Mexico for the inauguration of intensive excavation projects in these respective countries, to extend over a period of years, by Dr. Morley; 2. The discovery of new hieroglyphic inscriptions from Chichén Itzá, Ocosingo, Chiapa, Copán, and in the National Museum of Archaeology and History at Mexico City, by Dr. Morley; 3. The determination of the exact geographical positions by latitude and longitude of 12 of the most important archaeological sites in northeastern Petén, by Messrs. Love and Ricketson, being the seventh season of work in this region; 4. A topographical survey of Lake Petén, Guatemala, with special reference to the location and topographical characteristics of the ancient Itzá capital of Tayasal, by Mr. Kilmartin, being the third season of work at this site; and, 5. The preparation of the report on the archaeological sites along the east coast of Yucatán, with special reference to the ruins of Tulúm, by Dr. Lothrop, now in press (Lothrop 1924).

Dr. Morley left Washington on January 31, for Yucatán, to make arrangements for the visit of the President of the Institution and General Parsons of the Board

of Trustees, who followed a week later. The purpose of this trip was, by a first-hand examination of the ruins of Chichén Itzá to ascertain the nature of the archaeological problem at this site and how far the Institution' might cooperate in its solution.

The President and General Parsons returned to the United States after a fortnight's stay in Yucatán; and Dr. Morley, after a further examination of Chichén Itzá, left Yucatán on March 30 for Mexico City, to lay before the Direction of Anthropology of the Ministry of Agriculture and Public Works, in preliminary and unofficial conversations, the outline of a plan for archaeological investigations at Chichén Itzá by the Institution.

On April 16 Dr. Morley proceeded to Guatemala City, where he took up with Señor Abraham Cabrera, the Minister of Public Instruction, the question of securing a permit from the Government of Guatemala, under which excavations and archaeological studies might be carried on at any one or all of the three following sites: Uaxactún, Piedras Negras, and Tayasal, in the Department of Petén.

The permit obtained concedes, for a period of five years beginning January 1, 1924, the privilege of making excavations and archaeological studies at these sites under the direct supervision of the Minister of Public Instruction. It was, signed by that official on behalf of the Government of Guatemala on May 12 and delivered to Dr. Morley on May 23.

On the occasion of the formal organization of the Geological and Historical Society of Guatemala, Dr. Morley delivered an illustrated lecture, on the archaeological remains of the Republic, in the Palacio Centenario in the presence of President Orellana, the cabinet, and diplomatic corps. He returned Mexico on May 26.

The President of the Carnegie Institution arrived in Mexico City on June and at once began conferences with Dr. Manuel Gamio, the Director of Anthropology of the Mexican Government, as to the nature of the project to be undertaken at Chichén Itzá. Conferences were also had with Señor Don Ramón P. De Negri, the Minister of Agriculture and Public Works, and with General Obregón, President of Mexico, and on June 5 the formal proposition of the Institution was presented to the Mexican Government.

Dr. Morley spent the month of June in Mexico City arranging the details of the agreement with Dr. Gamio, of the Direction of Anthropology.

This contract (signed by the Minister of Agriculture and Public Works representing the Federal Government of Mexico) concedes to the Institution "permission to carry out archaeological explorations and excavations as well as all such repairs and restorations as may be necessary in the ruins of Chichén Itzá,

in the State of Yucatán, . . . for a term of 10 years beginning January 1, 1924."

Although the contract does not come into operation until January 1, 1924, under article 20 the right was given to commence immediately certain preliminary work, such as clearing away the forest growing over that part of the city which it is planned to excavate first, and constructing field-quarters for laborers and staff.

In conformity with this clause, Dr. Morley left Mexico City for Yucatán on July 12 and visited Chichén Itzá in company with Dr. Gamio and Mr. Reygadas of the Direction of Anthropology. The Group of the Thousand Columns was selected as the first point for intensive operations, and early in August the felling of the forest over this area was commenced, and the nature of the work to be undertaken was fully discussed with the responsible officials of the Mexican Government on the ground.

In December Mr. J. O. Kilmartin, by arrangement with the United States Geological Survey, went to Chichén Itzá to survey the property which it is proposed to rent for field-quarters and to make a preliminary map of the Group of the Thousand Columns, as well as to supervise the construction of additional quarters for members of the scientific staff and the Maya Indian laborers. Dr. Morley returned to the United States on August 29 and spent the autumn in organizing the Chichén Itzá project. The members of the staff are to take the field early in January 1924.

During the course of the field season it was possible, from time to time, to further the general work on the Maya inscriptions by the discovery of a few new texts, of which three were found to have Initial Series.

At Chichén Itzá on March 6 a new stela was found in the niche between the double stairway on the west side of the second terrace leading to the Caracol or Round Tower. This monument has 132 hieroglyphs sculptured on its front, sides, and top, and is the longest inscription yet found at this site. It has not yet been possible to decipher the date, although its hieroglyphs are well preserved.

Underneath this stela was found a large circular stone with a projection for tenoning it into a wall. On the front of the round part 12 human figures are sculptured in two lines before an altar, arranged as if engaged in some sacrificial rite. A double row of hieroglyphs around the periphery completes the carving on this unique piece of Maya sculpture.

Several new inscriptions were located in the National Museum of Archaeology and History at Mexico City; a small stela from Ocosingo, or more correctly from the archaeological site of Toniná near by and two stelae and a small round altar of unknown provenance, probably from the Usumacinta Valley.

The Toniná stela is short, like all the monuments at this site. Although it is not more than 4 feet [1.2 m] high, it is a perfect example of a Maya stela; the front is sculptured with a typical Maya figure, priest, ruler, or deity, holding in his arms the Ceremonial Bar. The back is inscribed with a double column of hieroglyphs surmounted by an Initial Series introducing-glyph. The inscription is badly effaced, though the katun coefficient is almost certainly below 11 and the tun coefficient is surely 0. The best reading of the, Initial Series would appear to be 9.7.0.5.9, though this is far from satisfactory.

The other two stelae mentioned above, as of unknown provenance, are, on stylistic grounds, probably to be assigned to the Usumacinta Valley. One of them has a human figure in profile upon its front and an Initial Series on its back. This reads quite clearly 9.12.0.0.0. The other, also sculptured with a human figure in side presentation on its front, has the day 9 Ahau carved in a conspicuous position before this figure. On the assumption that this day fell on a katun-ending, there are two possible readings in Baktun 9: 9.6.0.0.0, 9 Ahau 3 Uayeb and 9.19.0.0.0, 9 Ahau 18 Mol neither is particularly satisfactory, the former being as much too early as the latter is too late.

The small, round altar at the National Museum of Archaeology and History is a beautiful example of Maya sculpture from the Great Period of the Old Empire. It portrays a small, seated figure, facing to the left and holding in its hand a platter containing an object which may be the sun-sign. This is surrounded by a circle of 15 hieroglyphs of which the ninth (commencing at the top and reading clockwise) is the day 13 Ahau; the fifteenth is the day 9 Ahau. These two days are just one tun apart, if read in this order, and if it be assumed that the day 9 Ahau also corresponded with a katun-ending as well, the Initial Series, 9.19.0.0.0, 9 Ahau 18 Mol could be assigned to this piece, not an improbable reading on stylistic grounds.

Before leaving Mexico City, Dr. Morley also examined the important Stone of Chiapa,¹ through the courtesy of its owner, Señor Don Emilio Rabasa. This piece is only about one-third of the original monument, which must have been between 6 and 7 feet [1.8–2.1 m] high. The front is sculptured with the head and shoulders of a human figure facing to the left, with an elaborate head-dress; opposite the head are the remains of a single column of six or seven beautifully carved, but very small, hieroglyphs, each 1.5 inches [3.8 cm] square.

The significant point is that the first glyph which remains has a coefficient of nine surely, and the next one of 16, 17, 18, or 19;² and the next two possibly of 0 each. Could this be the Initial Series 9.19.0.0.0 with the Initial Series introducing-glyph effaced? The style of this monument indicates that dates from the most bril-

liant epoch of Maya art, namely, the Great Period of the Old Empire, 472–630 A.D.

It is the inscription on the back, however, which gives this monument its principal importance. This is presented in four columns, of five hieroglyphs each; the Secondary Series in the first two columns is apparent composed of eight orders of units, involving possibly the highest Maya time-period known, the great-great-great cycle.³ It is unfortunate, therefore that it has been impossible to connect this Secondary Series either with one or the other of the two Calendar Round dates on the back or with the other Secondary Series of 2.14.15 present.

The first week in May was devoted to excavating two small temple-sites at the ruins of Quiriguá, Guatemala: the Temple of Stela S in the banana fields of the United Fruit Company, about a kilometer southwest of the main group, and The Temple of Stelae T and U, about 1.5 km behind the Quiriguá Hospital, on the highest point of the first range of hills on the northern side of the Motagua Valley. The former proved to be only a foundation mound composed of two platforms, the lower 2 feet [61 cm] high with a battered wall, and the upper 4 feet [1.2 m] high with a vertical wall. On the summit were traces of a third very low platform, one step high. A stone stairway on the south side, now in ruinous condition, gave access to the summit. There were no vestiges of any former superstructure; and if this foundation mound had ever supported one, it must have been built of some perishable material. The monument associated with this mound, Stela S, stands about 50 yards [45.7 m] in front of the center of the south side, facing south, and dates from 9.15.15.0.0.

Very little material was recovered during the course of the excavations; no whole pieces of pottery, and only a few potsherds and obsidian flakes. These were turned over to the Minister of Public Instruction, in accordance with the terms of the permit, at the conclusion of the excavations.

The Temple of Stelae T and U was completely excavated. It faces the valley, that is, south, and contains but a single small chamber, 10 feet 2 inches [3.1 m] long by 3 feet 8 inches [1.1 m] wide, which had been floored with stone flags. A single doorway 5 feet 6 inches [1.7 m] wide in the southern wall gives access to it. The walls are 5 feet [1.5 m] thick. Further attempts were made to decipher the Initial Series of Stelae T and U, but unsuccessfully. The former dates surely from Katun 14, 9.14.0.0.0 being the best reading, and on stylistic grounds Stela U is probably not more than one katun later, that is, 9.15.0.0.0.

In 1921 a splendid cache of 24 eccentric-shaped flints (now in the Ministry of Public Works in Guatemala City) was found either in the southeastern corner of this chamber or in the hearting of the eastern

wall. The excavations this season yielded only a few obsidian flakes.

Dr. Morley was at Copán for three days in May. Three fragments of early stelae had been found, in tearing down the walls of the house at the west end of the block on the north side of the village plaza, and had been placed in the cabildo for safe-keeping. None has any decipherable calendrical hieroglyphs, but on stylistic grounds all three may be assigned to the early part of Baktun 9.

One of the most spectacular caches of jade in the Maya area was found on April 2, 1921, at Copán, just west of the northwest corner of the Mound 6 of Stela 7, in a cruciform vault below the foundation-stone of some Early Period stelae.

About 6 inches [15.2 cm] below the level of the cement floor on which the mound of Stela 7 was built, a large slab of stone 5 feet 1 inch [1.6 m] long, 2 feet 9 inches [84 cm] wide, and a foot [31 cm] in thickness was unearthed. This would appear to have been the foundation stone upon which one of the several Early Period stelae, found in the immediate vicinity, had rested, though just which one it is impossible to say. This foundation-stone in turn lay directly upon a large circular stone 3 feet 9 inches [1.1 m] in diameter and 9 inches [23 cm] in thickness, which in turn covered the cruciform vault. At the intersection of the axes of this vault was found the cache above mentioned. This contained the following objects of jade: one anthropomorphic statuette 7.25 inches [18.4 cm] high and weighing 2.5 pounds [1.13 kg]; eight jade pendants carved with representations of the human figure or grotesque animals; two pairs of round ear-plugs; and two long tubular beads. Also, there were 38 seashells, *Spondylus calcifer*; three shell beads; and a small quantity, perhaps enough to fill a two-ounce bottle, of quicksilver.

Two or three yards [1.8–2.7 m] east of this cache was found a human burial with a number of jade objects: beads, ear-plugs, and several small figures; also sea shells and quicksilver. In 1919 Dr. Morley found three pieces of beautifully worked jade not more than 4 yards [3.7 m] south of the above burial, in the northwest corner of this mound, practically on the surface: an anthropomorphic figure 3 inches [7.6 cm] high, pierced for use as a pendant, and the two halves of a jadeite pebble, from each of which a small cylinder had been cut out, probably for making into a pair of ear-plugs. Finally, the Museum of the American Indian, Heye Foundation, has a large jade pebble with a beautifully carved seated human figure on the front, which came from the cruciform chamber under the foundation of Stela 7 (Morley 1920:103–105).

The stylistic characteristics of these objects indicate that they all date from the Early Period of the Old Empire, which is in agreement with the dates actually

recorded upon the stela found on or around this mound, that is, 9.2.10.0.0 (Stela 24) to 9.9.0.0.0 (Stela 7). The jade objects found on or around this mound easily constitute the largest and most important collection of early Old Empire jades known anywhere.

The archaeological reason for this particular investigation was to ascertain the exact geographic positions of these different sites, from which data it would be possible to make an accurate map of the northern Petén region, that is, the very heart of the Old Maya Empire, showing the relative positions and distances apart of its largest centers.

The area in question is not large, a 50 mile square [129.5 sq km] in the northeastern corner of the Department of Petén practically comprises it, and none of these sites are far apart in an air-line.

Some surprising and, in view of existing highways of travel (the only too casual and round-about chicle trails), disconcerting facts developed there from. For example, it takes a mule-train, over existing trails, two days to go from Xmakabatún to Xultún, which are only 11.4 miles [18.4 km] apart, and other instances of the proximity of these cities one to another might be cited. Indeed, no two of them are so far apart as to require an Indian on foot more than a single day to travel between them, and some of them, as, for example, Tikal and Uolantún, are so close together, 3.5 miles [5.6 km], that they must be regarded as parts the same city.

Evidence multiplies that this section of the Old Empire was one of most densely populated areas of its size in the whole world during the first centuries of the Christian era, and the occupation of the land between different larger centers, like Tikal, Uaxactún, Xultún, Nakúm, Naranjo, etc., must have been practically continuous.

NOTES

1. Drawings of both sides of this stela were published by D. G. Brinton (1894: Fig. 82).

2. The drawing of the front of this monument published by Brinton (1894: Fig. 82), incorrectly shows this coefficient as 12. The original, however, has clearly three bars in addition to at least one dot.

3. Attention has already been called to the importance of this Secondary Series in *The Inscriptions at Copán* (Morley 1920:281). It appears to be composed of eight orders of units with the tuns omitted. The number probably recorded is 13.13.13.1.1.0.11.4. The only other Maya number known, involving eight orders of periods, is the Initial Series on Stela 10 at Tikal: 1.11.19.9.3.11.2.0.

4. The other objects which were found in this chamber were: A seashell (*Arca grandis*), a stone with a hole through it, an obsidian spearhead 7 inches [17.8 cm] long, another of the same material slightly longer, an obsidian knife 6 inches [15.2 cm] long, and a small fragment of an Early Period stela.

1.12.

SYLVANUS G. MORLEY
Archaeology

YB 23:209–211, 1924

Three separate expeditions were maintained in the field during the first six months of 1924, as follows: Dr. Morley, Messrs. Morris, Kilmartin, and Amsden in Yucatán, Mexico; Mr. Blom and Mr. Ricketson, in Petén, Guatemala; and Mr. Ricketson in British Honduras.

The several activities in Middle American Archaeological Research for the current year maybe described under four main headings as follows: 1. The lectures and conferences of Dr. Manuel Gamio, Director of Anthropology of the Mexican Government in the Administration Building in Washington in April; 2. The Chichén Itzá Project under Dr. Morley, Messrs. Morris, Kilmartin and Amsden, being the first season's work at this site; 3. The Uaxactún Project under Mr. Blom, being the eighth season's work in the Petén region, and the first season of intensive work at this site; and, 4. The excavations at Baking Pot, British Honduras, under Mr. Ricketson, the first season's work at this site.

Dr. Morley left Washington for Guatemala on February 5 to confer with governmental officials of that country with regard to archaeological investigations at the sites of Uaxactún and Tayasal in Petén.

Before leaving Guatemala, Dr. Morley delivered an illustrated lecture before the Geographical and Historical Society at the Palacio Centenario, covering the Institution's recent archaeological work in that country and in Mexico.

During the fall of 1923 a formal invitation had been extended by the President of the Institution to Dr. Manuel Gamio, Director of Anthropology of the Mexican Government, to deliver two lectures in Washington in the spring of 1924, upon the results of recent archaeological work in Mexico under the Director of Anthropology.

Dr. Gamio accepted this invitation, and these lectures were delivered at the Administration Building in Washington on the evenings of April 16 and 17. An exhibition of native Mexican arts and crafts, as revived by Dr. Gamio at San Juan Teotihuacán, was held in connection with his lectures, and a remarkable collection of paintings, pottery, tiles, textiles, basketry, and native jewelry was shown.

The lectures were followed by two archaeological conferences: one devoted to a discussion of the Chichén Itzá Project and general problems of archaeological research in Mexico, and the other more specifi-

cally to Dr. Gamio's own work in Mexico and his proposed classification of the several cultural horizons represented there. These conferences were attended by 25 representatives of the following institutions and organizations: American Museum of Natural History, New York; Archaeological Institute of America, Washington; Bureau of American Ethnology, Washington, DC; Carnegie Institution of Washington; Direction of Anthropology, Mexico; Museum of the American Indian, Heye Foundation, New York; National Geographic Society, Washington, DC; Peabody Museum of American Archaeology and Ethnology, Harvard University, Cambridge, MA; Phillips Academy, Andover, MA; University of Arizona, Tucson; and the United States National Museum, Washington, DC.

Dr. Gamio's lectures and the material he exhibited convincingly set forth the importance of the archaeological and sociological work now being carried on by the Mexican Government under his direction, and the conferences brought out a number of points relative to the conduct of archaeological investigations in Mexico, and served to clarify several issues under discussion.

On May 12 Dr. Morley and Messrs. Morris and Amsden left New Orleans for Yucatán to start work at Chichén Itzá, Mr. J. O. Kilmartin, of the United States Geological Survey, having proceeded thither six months earlier (November 1923) to commence the survey and basemap of the site.

The work at Chichén Itzá in 1924 falls under two headings: 1. The erection of quarters for the staff and laborers, and the repair of the buildings leased from Mr. E. H. Thompson, the owner of the hacienda of Chichén upon which the ruins are located, and 2. The excavations proper under Mr. Morris.

The property which has been leased by the Institution consists of the hacienda house and its outbuildings, and 100 acres of adjoining woodlands for the location of the necessary corn-fields and lime-kilns, and as a source of supply for building-stone, timber, and firewood.

It was impossible to undertake all of the necessary repair work on this property during the current field season, but new roofs were added to four buildings; one of the rooms was floored with cement for use as a store-house; and doors were fitted in several places where they were missing. A new two-room stone house with thatched roof was built for Mr. Morris, and the construction of quarters for the laborers was commenced along the south side of the principal square, which is to be known as the Park Chichén. It is estimated that at least 20 of these thatched dwellings will be necessary to shelter the required number of laborers.

Excavations closed at Chichén Itzá, on July 5, and Dr. Morley and Mr. Ricketson returned to the United States by way of New Orleans on July 17, the remain-

ing members of the staff proceeding thither by way of Veracruz and Mexico City on July 16.

Before leaving Yucatán Dr. Morley visited the island of Jaina, off the northwest coast, to examine a newly-reported hieroglyphic inscription. This trip was undertaken through information received from Mr. W. A. Sheetz of Mérida, who, together with Mr. Ricketson, accompanied Dr. Morley. The site is composed of half a dozen mounds, the easternmost of which is the second largest, being perhaps 30 feet in height. Fragments of two stelae were found at its northeastern corner, carved with representations of rulers and deities and columns of hieroglyphics; and one of these (Stela 1) proved to be of the very highest importance, no less, indeed, than the fourth Initial Series yet to be found in the entire New Empire region, that is, the peninsula of Yucatán.

The front of this stela is sculptured with nine human or divine figures, four seated across the top; 3, including the principal figure, standing in the middle; and two incomplete figures at the bottom. The sides and back are inscribed with hieroglyphs. The inscription begins on the left side with an Initial Series introducing glyph, but most unfortunately in view of the importance of the text, the rest of the Initial Series, save only for a part of the katun sign, is destroyed. The day-sign, Supplementary Series, and month-sign which are presented on the right side are, however, almost perfectly preserved. The day-sign is, either 12 Ahau or 13 Ahau, the former being the preferable reading; the month-sign is surely 8 Ceh. Possible Initial Series values corresponding to these two terminal dates follow, although this monument may be of much earlier date than either (Table 1.12.1).

Table 1.12.1. Calendrical Decipherments, Jaina.

11.18. 9.0.0	12 Ahau 8 Ceh	approx. 1329 A.D.
12. 5.15.0.0	13 Ahau 8 Ceh	approx. 1473 A.D.

In spite of the fact that only four Initial Series have yet been reported from the New Empire region, their distribution fairly well covers the peninsula of Yucatán from east to west: 1. At Tulúm on the eastern coast, 2. At Chichén Itzá in the northeastern quarter, 3. At Holactún in the northwestern quarter; and 4. At Jaina on the western coast. The particular value of this discovery lies in the fact that Initial Series stelae are so exceedingly rare from the New Empire that the few known constitute historical landmarks of first importance.

Dr. Lothrop's report (1924) on the ruins of Tulúm and the east coast of Yucatán was issued early in the spring. It contains 179 pages of text, 27 plates, of which five are in color, and 182 figures.

1.13.

SYLVANUS G. MORLEY
Archaeology

YB 24: 247–251, 1925

The activities in Middle American Archaeological Research during 1924 were concentrated at Chichén Itzá, Yucatán, Mexico, where the second season's [Chapter 1.12 this volume] excavations were commenced in February with a staff of follows: Dr. Morley, in charge; Mr. E. H. Morris, archaeologist in charge of excavations; Mr. Karl Ruppert and Mr. O. G. Ricketson, Jr., assistant archaeologists; Mr. E. L. Crandall, photographer (U. S. Department of Agriculture); and Miss E. H. Bayles, secretary and book-keeper. In addition, Mrs. E. H. Morris was of invaluable aid in copying the mural paintings from the Temple of the Warriors (Station 4) and in assisting Mr. Morris in connection with the excavations and repair work at Station 3.

Dr. Morley left Washington on December 19 for Mexico City, to confer with Mr. José Reygadas Vertiz, the newly appointed Chief of the Department of Anthropology, as to the plans for the coming field season, and reached Yucatán on January 12.

Work was commenced at Chichén Itzá on January 19, the first month being devoted to moving the equipment from Dzitas, the nearest railroad point to Chichén Itzá, 14 miles [22.5 km] distant by an automobile highway, repairing the field quarters, installing a gasoline pump and pressure tank, and clearing the forest growth from the high pyramid at the northwest corner of the Court of the Columns, where excavations were commenced on February 16.

During the short 1924 field season excavations had been carried on at three principal stations, all in the Group of the Thousand Columns, as follows: Station 1. The Northeast Colonnade; Station 2. The South Temple adjoining it; and, Station 6. The Small Ball Court.

During the current season excavations have been carried on at four additional stations, two in the Group of the Thousand Columns, one in the middle part of the city, and one at Old Chichén Itzá, as follows: Station 3. The temple on the northeast bank of the Xtoloc Cenote; Station 4. The Temple of the Warriors; Station 5. The Caracol; and, Station 7. The Temple of the Four Lintels, at Old Chichén Itzá.

Special reports describing these activities by Mr. Morris and Mr. Ricketson, and a report on the constructions in the Court of the Columns by Mr. Ruppert, will be found below.

GENERAL SUMMARY OF THE PRINCIPAL RESULTS OF THE YEAR

By far the most extensive piece of work undertaken this season was at the Temple of the Warriors (Station 4), which was completely cleared and partially repaired by Mr. Morris. The excavations proved that this building was one of the most important in the entire city; it is second only to the Castillo in point of size, and even exceeds the latter in wealth of sculptural decoration.

The pyramid supporting the temple proper covers two-thirds of an acre [2,700 square m], and rises in four retreating terraces to a height of 37 feet [11.3 m] above the general paved level of the Group of the Thousand Columns. The three lowest terraces have their cornices elaborately sculptured with jaguars, eagles, and another as yet unidentified animal with woolly covering, which were originally painted in brilliant colors. Only the top-most terrace seems to have been plain.

A steep stairway, 34 feet [10.4 m] wide, composed of 36 steps and flanked by two balustrades carved with representations of the feathered serpent, leads to the summit, where an imposing vista greets the eye.

The two massive feathered serpent columns, dividing the entrance into a triple doorway, rear themselves 15 feet [4.6 m] aloft, their massive heads resting on the ground, their tufted tail-rattles above. These were found scattered out in front of the temple and were restored to their original positions by Mr. Morris during the course of the excavations.

The temple proper is 69 feet square [6.4 square m] and is divided by a single partition, running north and south, into two chambers of equal size, 61 feet [18.6 m] long by 30 feet [9.1 m] wide, an outer chamber with a corbelled arch roof supported by 12 sculptured columns, and an inner sanctuary with eight sculptured columns, painted wall-benches at the north and south ends, and a magnificent altar or dais against the back or east wall, 13 feet 8 inches [4.2 m] wide, 8 feet 3 inches [2.5 m] deep, and 2 feet 8 inches [81 cm] high. This altar is supported by 19 painted Atlantean figures in an excellent state of preservation.

Both exterior and interior walls were elaborately painted, but the collapse of the entire roof has wrought irreparable damage to these once fine mural paintings. More than 800 stones, fallen from the roof and bearing fragments of these frescoes, were recovered during the excavations and removed to a storehouse at the hacienda for safe-keeping. Mrs. Morris copied in water-colors more than 200 of the best preserved of these before she returned the States. The subjects portrayed are gods, priests, warriors, men, animals, fish, and serpents, engaged in a variety of pursuits, offering in-

cense, fighting, rowing, swimming, fishing, etc. Marine subjects seem to have formed a large part of the design.

The outstanding features of The Temple of the Warriors are: 1. The three sculptured and painted terraces surrounding the pyramid on all four sides, with their imposing array of human and animal figures; 2. The sculptured and painted columns, of which there are 22; the two feathered serpent columns in the doorway, 15 feet [4.6 m] high; and the 20 inside, carved on all four sides with representations of gods, priests, and warriors, 12 feet [3.7 m] high. Originally, all of these had been brilliantly painted, and much of the pigment is still adhering; 3. The sculptured and painted altar against the back wall of the sanctuary, supported by 19 painted Atlantean figures; and, 4. The mural paintings.

Excavations were undertaken at the small temple on the northeastern bank of the Xtoloc Cenote (Station 3) which lies at the southwestern corner of the Group of the Thousand Columns, in the hope that some relationship might be established between it and the nearby cenote, which served as the chief source of the city's water supply in ancient times, and also because no single temple at this site previously had been completely excavated.

The most important feature of the temple was found to have been a handsomely sculptured panel on the back side of the arch in the sanctuary, directly above the altar. This had, originally been composed of five courses of sculptured blocks, each course containing six blocks, or a total of 30. Of these, only 19 were recovered, seven being found at considerable distances from the temple, whither they had been carried in Spanish times to build a rough stone wall. Fortunately, five of the six blocks forming the middle of this panel were found. These present two warriors, elaborately clothed, having head-dresses, of sweeping plumes, and a hissing, feathered serpent above the head of each. The border, of which more than half was recovered, is composed of flowering vines, with birds here and there. This panel is one of the most notable sculptures in the city, not only because of its unique location on an arch, being the only example of its kind yet found at Chichén Itzá, but also because of the presence of flowers and vines, an unusual subject in Chichén Itzá bas-reliefs.

Another important undertaking of the season was the repair of the upper part of the Caracol or Astronomical Tower (Station 5). This structure is the only one of its kind in the city and, with the exception of the round tower at Mayapán, the only one known in the Maya area.

The upper part, containing several small passageways which were used as lines of sight in making astronomical observations, was in a highly ruinous condition, and immediate repair-work was impera-

Figure 1.13.1. Chichén Itzá, Caracol, hieroglyphic fragment.

tive if these lines of sight were to be saved from shifting, owing to the crumbling condition of the masonry. This work was successfully carried out by Mr. Ricketson, and the entire upper part of the tower so strengthened with cement and masonry that the danger of any shifting of the lines of sight from their present positions has been eliminated.

Mr. Ricketson finds that the principal passageway still standing, that looking west, would seem to have been used in determining the dates of the equinoxes and the summer solstice.

During the excavation, of the Caracol, several fragments of a hieroglyphic band came to light. One of these, shown in Figure 1.13.1, was of especial interest as follows: 3 Imix 9 Yax, Tun 1. New Empire dates are rarely as carefully recorded as those of the Old Empire, but the intent here would seem to have been, fairly clear, to indicate the day 3 Imix 9 Yax falling in some Tun 1. An examination of Goodman's chronological tables show that the only place where this day occurred in a Tun 1 within the limits historically possible at Chichén Itzá was at the position 11.16.0.4.1, 3 Imix 9 Yax, corresponding to 1280 A.D., which therefore is probably the date recorded upon this fragment.

Just before the close of the field season, excavations were undertaken at a small temple in Old Chichén Itzá (Station 7), where in 1911 Mr. E. H. Thompson had found two hieroglyphic lintels, in the hope that more of these exceedingly valuable texts might be found. This operation was under the supervision of Mr. Ricketson and two additional inscribed lintels were discovered there on May 22 and 26 respectively, both of which are practically in "mint state." One has 72 glyph blocks, and the other 80. Because of this discovery this structure was renamed "The Temple of the Four Lintels."

Table 1.13.1. Stelae with Tun 13 and 1 Ahau Dedication Dates, Chichén Itzá and Yulá.

<i>Lintel</i>		<i>Tun 13</i>	<i>1 Ahau</i>
1	Temple of the Four Lintels ¹	Glyph 13	Glyph 14
2	Temple of the Four Lintels	5	6
2	Temple of the Four Lintels,	40	41
3	Temple of the Four Lintels	2	
3	Temple of the Four Lintels	74	75
4	Temple of the Four Lintels	14	15
1	Temple of Two Lintels, Yulá		15
2	Temple of Two Lintels, Yulá	2	4
2	Temple of Two Lintels, Yulá		64

1. (Chichén Itzá)

At Yulá, 5 miles [3.1 km] south and slightly east of Chichén Itzá, there is a small temple having two hieroglyphic lintels of a similar character. Dr. Morley made a comparative study of these six lintels, and found that all of them, both the two at Yulá, as well as the four in Old Chichén Itzá, were apparently dedicated on the same day, namely a Tun 13 ending on a day 1 Ahau. The following table shows the position on each of these lintels where this particular tun and day are recorded, in some cases as often as twice on the same lintel (Table 1.13.1).

Nor do the similarities between these six lintels end here. The date 9 Lamat 11 Yax is recorded thrice at the Temple of the Four Lintels, as follows: on Lintel 1, by Glyphs 9 and 11; on Lintel 3, by Glyphs 70 and 72; and on Lintel 4, by Glyphs 9, 11, and 12.

Finally, the fronts of Lintel 1 at Old Chichén Itzá and Lintel 1 at Yulá have the same figure of a bird carved upon them, with a human head issuing from the bird's opened beak. And again, Lintel 4 at Old Chichén Itzá and Lintel 2 at Yulá both have the same figure of a serpent carved upon them, with a human head issuing from the gaping mouth; the two pairs being practically identical in design:

As has been pointed out in a previous *Year Book* [Chapter 1.6 this volume], the method of dating used in the New Empire was much more abbreviated and correspondingly less accurate than the Initial Series dating of the Old Empire. Thus any given tun, as 13 here, for example, ending on any given day, as 1 Ahau here, could recur, fulfilling these two conditions, at intervals of every 256.25 years. Fortunately, in the present case the historical probabilities limit the possible Initial Series values to one of two readings: 11.9.13.0.0, 1 Ahau 13 Pop, which corresponds to the year 1155 A.D., or 12.2.13.0.0, 1 Ahau 13 Chen corresponding to the year 1411 A.D. Of these the former appears the better reading since the latter was within 35 or 40 years of the final abandonment of the city, when decadence already must have set in, and when it would have been practically impossible

to have executed such beautiful sculptures as these lintels.

The endings of Tun 13 appear to have been of especial significance to the ancient Maya, even from early Old Empire times (Morley 1920:358), and it is therefore not surprising that this particular Tun 13 should have been so scrupulously recorded on these six lintels, all of which appear to have been dedicated upon this date.

The other date, 9 Lamat 11 Yax, recorded on three different lintels in the same temple, appears to have had the Initial Series value 11.8.19.5.8.¹ This is practically within one day of being exactly 13.5 solar years earlier dedicatory date, or exactly eight Venus years of 584 days and one tzolkin or 260-day period, earlier.

On February 26, the President of the Institution and Dr. Wissler and Dr. Kidder of the Advisory Committee arrived at Chichén Itzá for a visit of 10 days. Technical and other problems arising from the excavations were discussed, and a closer contact was established between the members of the committee and the staff.

Excavations were brought to a close on June 20, although Mr. Morris and a corps of masons continued working at certain urgent repairs on the Temple of the Warriors for another fortnight. The experience of the past two seasons tends to indicate that excavation can not be carried on profitably long after the middle of June. By that time the rainy season in Yucatán is well under way, and, what with necessary time out for the heavy afternoon showers as well as the resultant flooding of the diggings, the work is retarded and operations are not only unprofitable but also unsatisfactory.

Mr. Crandall returned to the United States by way of New York on June 9. Dr. Morley and Mr. Ruppert left Yucatán on June 27, going by way of Veracruz and Mexico City, where Dr. Morley discussed with Mr. Reygadas a number of problems which had developed during the season, as well as preliminary plans for next year. In developing the Chichén Itzá Project, the policy has been from the beginning to consult frequently the Mexican officials concerned, in order that there should be entire agreement at all to the work done, and the best interests of the research thus secured.

Mr. and Mrs. Morris, Mr. Ricketson, and Miss Bayles returned to the United States by way of New Orleans early in July, thus bringing to a close the activities of the second field season.

NOTES

1. This date was at first erroneously deciphered as 9 Eznab 11 Yax with the Initial Series, a value 11.7.12.16.18 [Chapter 1.6 this volume] and was so used by Spinden (1924:281) but a re-examination this season of the day-signs,

on Lintels 3 and 4, as well as on the newly discovered Lintel 1, all at the Temple of the Four Lintels, demonstrated beyond any doubt that the day-sign in each case is Lamat and not Eznab, and the corresponding Initial Series value probably 11.8.19.5.8.

1.14.

SYLVANUS G. MORLEY

Archaeology

YB 26:231–240, 1927

Two principal investigations were carried on during 1927 in Middle American archaeological research as follows: 1. The Chichén Itzá Project; and, 2. The Uaxactún Project.

In addition to these two projects, two expeditions were sent out from Chichén Itzá, Yucatán, Mexico, and one from Uaxactún, Petén, Guatemala: 3. The Edzná Expedition; and, 4. The Muralla Expedition.

The Chichén Itzá Project completed its fourth field season on May 28, although minor repair operations continued for another two months.

The staff for 1927 was as follows: Sylvanus G. Morley, in charge; E. H. Morris, archaeologist-in-charge of excavations; Karl Ruppert, P. S. Martin, H. B. Roberts, and R. A. Franks, assistant archaeologists; Jean Charlot, Mrs. E. H. Morris and Lowell Houser, artists; E. L. Crandall (U. S. Department of Agriculture), photographer; Miss Katheryn MacKay, housekeeper and trained nurse; Miss N. E. Piatt, secretary and book-keeper; L. C. Hammond, mechanic; and Gustav Strömsvik, carpenter.

Dr. Morley left Washington on December 14 for Mexico City to discuss the plans for the current field season with Mr. Jose Reygadas Vertiz, the Director of Archaeology of the Mexican government. While there he delivered two illustrated lectures in Spanish: one, under the auspices of Dr. J. M. Puig y Casauranc, the Minister of Public Education, upon the results of the Institution's work at Chichén Itzá in 1926; and the other upon the Institution's larger program of archaeological investigations in the Maya field, before the Sociedad Antonio Alzate, the leading scientific society of Mexico. He reached Yucatán on January 20 where excavations were already under way in charge of Mr. Morris.

Through an arrangement with Dr. E. A. Hooton of the Bureau of International Research of Harvard Uni-

versity and Radcliffe College with a grant from the Laura Spelman Rockefeller Fund, Dr. and Mrs. G. D. Williams were sent to Chichén Itzá in February for a period of eight months to make anthropometric studies of the native Maya Indians of the region. In return for the facilities of the Institution's establishment at Chichén Itzá, laboratory, photographic services, field quarters, and board, Dr. Williams served as the physician of the Project, and also made basal metabolism tests both upon the Indians and the white staff, for the Department of Nutrition. It was agreed that both parties should have access to the results of the joint investigation, and the right to utilize them, giving proper acknowledgment in either case to the other party. In the metabolism tests, Dr. Williams used a Benedict Portable Student Apparatus and made an examination of 19 members of the staff and 36 natives. He found the natives running uniformly around 10 percent higher than the staff members, practically all of them on the plus side.

Through the generosity of two groups of friends of the Chichén Itzá Project, the excavation and repair of two smaller temples were made possible. Through funds provided by General William Barclay Parsons, Major L. G. Reed, Mr. W. C. Osborn and Dr. S. McCullough of New York City, the Temple of the Two Lintels at Old Chichén Itzá, was excavated and partially repaired; and through a gift from Dr. F. I. Proctor of Boston and Mrs. E. C. Ritchie of Baltimore, the Temple of the Wall Panels belonging to the Caracol Group was excavated and repaired.

Again the Project has benefited greatly from Dr. Proctor's skill in stereoscopic photography. During the two months he and Mrs. Ritchie were at Chichén Itzá, they exposed more than 500 stereoscopic negatives with highly satisfactory results. The peculiar perspective properties of stereoscopic photography make it the very best method of recording stone-carving. It renders the depth of the relief with a verisimilitude unattainable with any other type of camera.

In March Mr. Reygadas and Mr. Enrique Juan Palacios, of the Direction of Archaeology, and Mr. Frederico Mariscal, one of the leading architects of Mexico, visited Chichén Itzá on behalf of the Mexican government. Technical problems arising from the excavations and repair-work were discussed with Dr. Morley and Mr. Morris and, as a result of Mr. Reygadas' visit, it was decided that the Direction of Archaeology would continue the repair of the Castillo with the fund provided by the Ministry of Public Education.

Urgent repairs had been made to the Castillo proper in 1926 under the able supervision of Mr. Eduardo Martinez Canton and Mr. J. M. Erosa Peniché, the local representatives of the Direction of Archaeology, and during the current season this work was continued,

as well as the replacement of the facing of the north and east sides of the pyramid, an enormous undertaking. For close on to two centuries, the Castillo has served as a quarry for faced stone for the village of Pisté, a mile and a quarter [2 km] northeast of Chichén Itzá, with the result that much, if not most, of the original facing has been removed. Before leaving, Messrs. Reygadas, Palacios and Mariscal expressed themselves as highly satisfied with the work that had been done by the Institution at Chichén Itzá; and not a little astonished at the magnitude of the operations, and the amount accomplished since Mr. Reygadas' last visit in 1925.

Excavations at Chichén Itzá during the current year were carried on at eight stations as follows: Temple of the Warriors (Station 4). Northwest Colonnade (Station 10); North Colonnade (Station 8); West Colonnade (Station 9); Caracol (Station 5); Temple of the Wall Panels (Station 14); Temple of the Interior Atlantean Columns and the House of the Grinding Stones (Station 11); and, Temple of the Two Lintels (Station 7), Old Chichén Itzá.

Special reports covering the excavations at the Temple of the Warriors by E. H. Morris, at the Caracol and at the Temple of the Wall Panels by Karl Ruppert, and upon the art work by Mr. Charlott will [follow].

The outstanding accomplishment of the year at Chichén Itzá was the completion of work (both excavation and repair) at the Temple of the Warriors and the Northwest Colonnade in front of it, which has been the principal center of operations during the preceding two field seasons [Chapters 1.13 and 1.14 this volume].

When excavations were begun at the Temple of the Warriors in February 1925, it appeared to be little more than a forest-covered mound, some 50 feet [15.2 m] in height, its steep, even precipitous, sides showing loose stones lying here and there. Near the top at the east a cornice could be distinguished for a few feet; and on the very summit the tops of some square columns. For the rest it was a tangle of thick undergrowth with a respectable number of considerably higher trees. Little was it anticipated that this apparently plain and uninteresting mound represented all that was left of what had been the most elaborate and magnificent building in the city.

The excavation of the temple proper was completed in 1925. Its repair and that of the greater part of the supporting pyramid, including the replacement of fallen sculptured elements wherever possible, and the excavation of the Northwest Colonnade directly in front of it occupied the greater part of the 1926 season. Finally the excavation and the very extensive repair work upon the earlier temple buried in the northwestern corner of the supporting pyramid were the principal

activities of the current season. There has resulted from this great undertaking what is unquestionably the most impressive and beautifully decorated building at Chichén Itzá, if not indeed in the whole Maya area.

Another important center of investigation, where excavation and repair have been going on for three years, is the Caracol, or Astronomical Observatory. This massive round tower, rising from a double terraced platform, is unlike every other building in the city; and its function as being a place from which astronomical observations were made, early marked it for special study by the Institution. During the present year, the excavation of the interior and exterior corridors was completed, and the necessary repairs were carried to the point that it should be possible to finish the preservation of this highly important construction, perhaps the most important in the city from a purely scientific point of view, in another field season.

A third center of investigation has been the section known as Old Chichén Itzá, stretching from 0.5 to 2 miles [0.8–3.2 km] south and slightly west of the area included in the original base-map, surveyed by J. O. Kilmartin in 1924 [Chapter 38.2 this volume].

The discovery here of a re-used hieroglyphic lintel presenting a Baktun 10 Initial Series, not only the single Initial Series thus far found in the city, but also the earliest, contemporaneous date, suggested the name Old Chichén Itzá, by which this temple is known.¹ Excavations were commenced here in 1925 at the Temple of the Four Lintels (Station 7), and resulted in the discovery of two more hieroglyphic lintels [Chapter 38.7 this volume]. In 1926 excavations were carried on at several places in the Group of the Initial Series (Station 13) [Chapter 38.9 this volume]; and again during the current season in the Temple of the Two Lintels, and Temple of the Lintel (Station 7) where three new hieroglyphic lintels were discovered on May 6 and 19, respectively. These latest finds, together with the discovery of a fourth hieroglyphic lintel built into a stone water-trough at the old abandoned plantation of Jalacal, 3 miles [4.8 km] east of the center of the city make a total of 20 hieroglyphic lintels² now known at this site, distributed [in Table 1.14.1].

A comparative study of these 20 lintels made by Dr. Morley during the present season has yielded interesting results, among others the probable dedicatory date of the second story of the Monjas, one of the most important structures in the city from an architectural point of view, since it is the largest building now extant, dating from before the Toltec conquest in 1191 A.D.

With the single exception of the Initial Series lintel, the other 19 lintels present either Period Ending dates, tzolkin dates⁴ or no dates at all, at least not recognizable as such in the present state of knowledge.

Table 1.14.1. Distribution of Hieroglyphic Lintels, Chichén Itzá and Jalacal.

<i>N</i>	<i>Provenance</i>
2	Temple of the Two Lintels at Yulá, 4 miles [6.4 km] southeast of Old Chichén Itzá

1	Water trough in front of the plantation house at Jalacal
20	Total

This leaves for chronological comparisons: one Initial Series date; 11 Period Ending dates; and five tzolkin dates. Three of the lintels are without recognizable dates.

The dedicatory date of the Initial Series lintel is 10.2.10.0.0, 2 Ahau 13 Chen. This and the accompanying Initial Series are the most accurately fixed dates in Yucatán, and may be utilized as such in any chronological investigations.

The 11 Period Ending dates are by no means equally clear. For example, owing to some sort of an error, apparently in the original inscription, it has been impossible to assign any satisfactory date to the lintel found in the water-trough at the plantation of Chichén Itzá, and this in spite of a close first-hand study of its inscription.

Again in the case of the lintel in the water-trough at the plantation of Jalacal, part of the upper row of hieroglyphs was battered off in reshaping it for this secondary use, so that the upper four-fifths of the Period hieroglyph are gone. The same condition, due in this case, however, to a natural break, has partially destroyed the Period hieroglyph on the south lintel of the Temple of the Two Lintels at Yulá. And, finally, although the reading suggested for the date of the lintel in the Akabtzip is probably correct, it is not certainly so. These last three dates, however, are probably correctly deciphered, as given [in Table 1.14.2].

Any one of these dates could, and did, recur at intervals of every 260 tuns or 256.25 years, but since all of these lintels may be assigned to a period before the Toltec conquest in 1191 A.D., on stylistic grounds, it has been possible in each case to fix the corresponding Initial Series date with a considerable degree of accuracy [Table 1.14.3].

An examination of the preceding table at once discloses one very suggestive point, that every one of these 10 Period Ending lintels, whatever may be the number

Table 1.14.2. Calendrical Decipherments, Lintel Inscriptions, Chichén Itzá, Jalacal, Yulá.

Temple of the Two Lintels at Yulá	2 lintels	Tun 13 ending on a day 1 Ahau
Temple of the Four Lintels, Old Chichén Itzá	4 lintels	Tun 13 ending on a day 1 Ahau
Water trough at Jalacal	1 lintel	Tun 13 ending on a day 1 Ahau
Temple of the Two Lintels, Old Chichén Itzá	1 lintel	Tun 10 ending on a day 1 Ahau
Temple of the Lintel, Old Chichén Itzá	1 lintel	Tun 1 ending on a day 1 Ahau
Akabtzip	1 lintel	Tun 1 ending on a day 1 Ahau

of the particular tun-ending, which was recorded (that is, in seven cases, a tun 13; in one case, a tun 10; and in two cases, a tun 1) ends on the same day, namely 1 Ahau).

It is, of course, true that all the tuns of Maya history ended on some one of the 13 days Ahau, as 1 Ahau, 2 Ahau, 3 Ahau, etc., but that these 10 lintels, the only 10 recording decipherable Period Ending dates thus far found at Chichén Itzá, representing six different buildings in four widely scattered sections of the city, should all end on the same day, when the chances are 13 to one against it, seems to place this phenomenon beyond the range of reasonable coincidence, and strongly suggests that for some esoteric reason, the priestly caste, which decided such matters, deliberately chose tuns ending upon the day 1 Ahau for the dedication of their temples, perhaps as being the most auspicious.⁵

The dating of the Temple of the Two Lintels (Station 7) at Old Chichén Itzá as 11.2.10.0.0, 1 Ahau 3 Uayeb (1014 A.D.) has probably made possible the correct dating of the second story of the Monjas, which has long been a matter of considerable importance, because of the key position occupied by this building in the architectural sequence at Chichén Itzá.

The excavation of the Temple of the Two Lintels at Old Chichén Itzá carried out this season very clearly established its close stylistic relationship with the Monjas Group, many of the decorative elements in the former building being duplicated in different units of the latter.

Take, for example, the lattice-work motif composed of X-shaped elements, which also occurs in the East and Southeast Annexes of the Monjas, the Iglesia and the Red House; or again a highly specialized dentated motif, found also in the second story of the Monjas, and in the Iglesia even as a cornice, exactly as in the Temple of the Two Lintels; a grecque motif found in the foundation platform of the East Annex of the Monjas, and in an identical position in the Temple of the Two

Table 1.14.3. Calendrical Decipherments, Initial Series Dates, Yulá, Chichén Itzá, Jalacal.

Temple of the Two Lintels, Yulá	2 lintels	11.9.13.0.0	1 Ahau 13 Pop	1155 A.D.
Temple of the Four Lintels, Old Chichén Itzá	4 lintels	11.9.13.0.0	1 Ahau 13 Pop	1155 A.D.
Water trough, Jalacal	1 lintel	11.9.13.0.0	1 Ahau 13 Pop	1155 A.D.
Temple of the Two Lintels, Old Chichén Itzá	1 lintel	11.2.10.0.0	1 Ahau 3 Uayeb	1014 A.D.
Temple of the Lintel, Old Chichén Itzá	1 lintel	11.7.1.0.0	1 Ahau 13 Kankin	1014 A.D.
Akabtzip	1 lintel	11.7.1.0.0	1 Ahau 13 Kankin	1014 A.D.

Lintels. Indeed, it is not overstating the case to say that the stylistic affinities between this temple and the Monjas Group are closer than are the stylistic affinities of either to any third building or group of buildings in the city. *A priori* this would indicate that they both probably date from approximately the same period.

It has been explained above that five of the seven hieroglyphic lintels in the second story of the Monjas commence with the same day, namely 8 Manik, but as there are no other recognizable calendric hieroglyphs either on these six lintels, or on the remaining two, and as this day 8 Manik or any other day of the tzolkin could, and did, recur after intervals of every 260 days, the resulting accuracy in any period of time above a year is negligible.

The day Manik, or to be more exact the 13 different days Manik, are among the only 52 days of the tzolkin, with which the Maya New Year (0 Pop) could begin, and the not unreasonable assumption was made that the day 8 Manik, recorded five times in the second story of the Monjas without its corresponding month positions, was in reality a Maya New Year's Day, written 8 Manik 0 Pop, which at once reduced the possible occurrences of this date from once or even twice in the same year to but once every 52 years.

Nor is this assumption especially far fetched, since all the original sources the inscriptions on stone, the codices, the Books of Chilam Balam and the early Spanish authorities, agree that the Maya New Year began with the first day of the month Pop, written in Old Empire times and probably far down into New Empire times as 0 Pop.⁶

It must be borne in mind in this connection, that the Calendar Round Date 8 Manik 0 Pop, or any other in fact, recurred throughout Maya history at 52-year intervals, and that therefore the maximum distance this date could be from any other date was only 26 years, since any distance over 26 years would bring it that much nearer its next recurrence, as for example 30 years after one occurrence would bring it within 22 years, that is, 22 years, before its next occurrence.

The next problem was to ascertain how near the date of the Temple of the Two Lintels at Old Chichén Itzá, that is, 11.2.10.0.0, 1 Ahau 3 Uayeb,⁷ this Calendar Round date 8 Manik 0 Pop could occur. This was found to be exactly five true solar years later with an error of less than one day (Table 1.14.3).

Table 1.14.4. Calendrical Decipherments, Temple of the Two Lintels Calendar Round Date, Chichén Itzá.

11.2.10.0.0	1 Ahau 3 Uayeb	1014 A.D.
11.2.15.1.7.8	8 Manik 0 Pop	1019 A.D.

But the Maya number, five tuns (5 x 360), one uinal (1 x 20) and seven kins (7 x 1), equals 1,827 days, which in turn equals five years of 365.25 days each, and a remainder of 0.75 of a day; but, since the ancient Maya did not know the use of fractions, this was as near as they could come in their arithmetical notation to recording five true years. Had the ancient Itzán priests used 1,826 days instead of 1,827 here, the count would have fallen one-fourth of a day short of five true years, and one day short of a Maya New Year's Day, reaching instead the day 11.2.15.1.6, 7 Cimi 4 Uayeb.

The Temple of the Two Lintels at Old Chichén Itzá was probably erected to commemorate the *lahuntun* ending 11.2.10.0.0 as we have seen, and the second story of the Monjas, the most beautiful unit of the whole Monjas Group, was dedicated on a Maya New Year's Day, exactly five true years later.

The larger significance of these new discoveries lies in the light that they throw upon the chronological sequence of architecture at Chichén Itzá.

With the help of an increasing number of fixed dates recorded in a chronological system, which is one of the most beautiful and accurate time counts ever devised by the human mind, and with the help of our increasing knowledge of the stylistic characteristics of Maya arithmetic, it is becoming possible to assign the more important buildings to their proper positions in the chronological sequence.

No structures have yet been found at Chichén Itzá which may be referred with any degree of certainty to the first period of the city's occupancy, the so-called Colonization Period from 531 to 699 A.D.; indeed but one datable object has been recovered, assignable thereto, namely the Initial Series lintel, which had been re-used, possibly in the walls of the Temple of the Initial Series⁸ at Old Chichén Itzá, a structure surely dating from late Toltec times.

Thanks to these recent chronological discoveries and to a utilization of the stylistic criteria present in the buildings themselves, it has been possible to assign a number of different structures to the second, or Renaissance, Period as follows: the Temples of the Lintel, the Two Lintels and the Four Lintels at Old Chichén Itzá; the Temple of the Two Lintels at Yulá; the Temple of the Lintel at Jalacal; the Akabtzip; the Iglesia, the East Annex of the Monjas, the Red House and the House of the Deer, in the central part of the city. All these buildings date from a period prior to the Toltec conquest, when Maya architecture still retained its original flavor, unmodified by alien influence; and before the influx of Toltecan ideas and building practices from the highlands of central Mexico had produced the Toltec-Maya hybrid, which is the Chichén Itzá of the third and greatest period.

From this third, or Toltec Period, 1191 to 1448 A.D., date the Caracol, the Temple of the Wall Panels, the Temple of the Xtoloc Cenote, the High Priest's Grave and adjoining structures, the Castillo, the Ball Court, the Temple of the Cones, the Temple of the Eagles, the Via Sacra, most if not all of the Group of the Initial Series, and the vast architectural complex called the Group of the Thousand Columns, and all of its associated structures, as well as many other smaller groups.

Previous to the present season 9 Chac Mool statues had been found at Chichén Itzá, distributed as follows: 1. At the point where the Via Sacra leaves the Great Terrace; 2. Just east of the Temple of the Eagles; 3. Buried in the substructure of the Temple of the Eagles (now in the National Museum at Mexico City); 4. Probably found in the same place as no. 3 and removed thence by Augustus Le Plongeon, and abandoned by the roadside just west of the southern open end of the Ball Court (now in the Museum of Archaeology and History at Mérida); 5. Just east of the Temple of the Cones, probably the largest; 6. In front of the Temple of the Warriors; 7. In front of the temple on the east side of the Court of the Thousand Columns; 8. In the bush about 200 yards [182.9 m] west of the Monjas; and, 9. In front of the Temple of the Initial Series at Old Chichén Itzá.

In addition to these, three others were found during the current season as follows: 10. In the North Colonnade in front of the sculptured and painted dais; 11.

In the temple buried in the northwestern corner of the pyramid supporting the Temple of the Warriors, that is, the Temple of the Chac Mool; and, 12. At the western side of the Group of the Initial Series at Old Chichén Itzá.

With the possible exception of no. 3, the newly discovered no. 11 is the best preserved of this type of statues thus far recovered.

An increasing efficiency on the part of the native laborers has been noted during the current year. The Chichén Itzá Project has now completed four field seasons; some of the laborers have been with the Project since its first year, and the great majority have served for at least two seasons. This is particularly noticeable among the masons, who have grown to understand the peculiar demands of the repair-work, and who, in some cases, have developed a real appreciation of, and feeling for, the "old" quality of the stone work. Even the shovel, pick and wheel-barrow men have become more proficient in handling these implements, so that the excavations have proceeded not only more smoothly, but more rapidly. To this increased efficiency of the native labor is due in no small part the greater amount of work accomplished in the 1927 field season as compared with any one of the preceding three seasons.

Through an arrangement reached with Mr. Reygadas during his visit to Chichén Itzá in March, it was decided to turn over to the Mexican government at the end of the season (May 28), the material excavated during the first year (1924) and also the great bulk of the stones from the Temple of the Warriors showing fragments of the original frescoes, which Mrs. Morris had either copied or rejected as too incomplete and fragmentary for record.⁹ Thirty-eight stones only were reserved for further study. In addition to the foregoing material, custody was released of a number of sculptures, loose pieces, statues, Atlantean figures, carved panels and lintels, elements which would never be replaced in their original positions in the façades.

Mr. Reygadas has decided to deposit the greater part of the portable material resulting from the Institution's excavations at Chichén Itzá in the Museum of Archaeology and History at Mérida, an organization supported by the State of Yucatán, the Director of which is Mr. Luis Rosados Vega. Mr. Rosados visited Chichén Itzá at the beginning of June when Dr. Morley relinquished custody of this material to Mr. Eduardo Martínez Canton, the local representative of the Direction of Archaeology, who in turn gave it to Mr. Rosados Vega. A special exhibition hall, called the "Salón Carnegie," has been opened in the Museum in Mérida for the display of the material and proper credit given the Institution for having been responsible for its acquisition.

The principal additions to the staff-quarters at Chichén Itzá during the year were the erection of a house for Dr. Morley, on the hill just east of and adjoining the former chapel of the plantation, and the conversion of the building formerly used as a school-house into a four-car garage.

Larger operations closed at Chichén Itzá on May 28, at the end of the ninth fortnight of excavations. Minor excavation and repair-work continued at the Temple of the Warriors and the Temple of the Two Lintels at old Chichén Itzá for another month, until June 25, and repair-work at the Temple of the Wall Panels for still another month, or until July 23.

Just after the close of larger operations, on June 4 and 5, Dr. Morley and Messrs. Ruppert and Charlott visited the ruins of Yaxuná, 15 miles [24.2 km] south and slightly west of Chichén Itzá. This site, according to the accounts of Indians of the region, is the western terminus of the stone causeway, which starts at Cobá, 75 miles [120.8 km] east of Yaxuná. The eastern terminus was explored last year for a distance of nine miles [14.5 km] west from Cobá, but without reaching its end; and during the intermediate season (July to December 1926), Juan Olalde, the head foreman at Chichén Itzá, had pushed eastward from Yaxuná for a distance of 15 miles [24.2 km], also without coming to its end. Finally since 12 sculptured stelae had been found at Cobá, the eastern terminus last year [Chapter 34.1 this volume], it was hoped that others might be found at the western terminus this year, which was the immediate object of this visit.

No sculptured stones of any sort were found, and only a few dressed blocks. Only one building is standing, and its masonry is altogether different from that of Chichén Itzá and more like the remains at Cobá, great masses, composed of roughly shaped, undressed stones or even more like the buildings at Edzná on the other side of the peninsula, where the dressed blocks are small in size and comparatively few in number. This is very different from conditions at Chichén Itzá, where there is a wealth of dressed blocks, standing in walls, lying strewn about through the bush near every fallen building, and even built into masonry fills. Yaxuná has a very large Acropolis surmounted by two lofty pyramid-temples, standing side by side, both facing north. It is obviously of much earlier date than Chichén Itzá.

Its proximity to Chichén Itzá, on the other hand, being only 12 or 14 miles [19.3–22.5 km] distant in an air-line, as well as the fact that it stands at the western end of the great Cobá-Yaxuná highway, strongly suggests that it was an important center, and possibly may have been the one from which Chichén Itzá was first colonized.¹⁰

NOTES

1. This lintel was discovered by E. H. Thompson in 1900 (Morley 1920:500).

2. The Temple of the Xtoloc Cenote (Station 3) has a carved lintel but no hieroglyphs.

3. This lintel is now in the Museum of Archaeology and History at Mérida.

4. Five of the seven hieroglyphic lintels in the Monjas commence with the same day, 8 Manik, one of the 260 different days of the tzolkin or "count of days," used by the ancient Maya priests in casting horoscopes and making divinations. Since any given day of the tzolkin, for example 8 Manik, recurred at intervals of every 260 days, this type of date, without additional chronological data, is practically useless for fixing the age either buildings or monuments.

5. These 10 examples may be increased to 11 by the addition of a painted capstone found by Dr. Morley in the Temple of the Owl at the Group of the Initial Series (Station 13) at Old Chichén Itzá in 1913. The painted inscription on this capstone began with the day 1 Ahau, ending on a Tun 13. But since the Temple of the Owl very surely dates from the Toltec Period (that is, after 1191 A.D.) the corresponding structural position of this particular day 1 Ahau ending a Tun 13 is in all probability 12.2.13.0.0, 1 Ahau 13 Chen, or 1411 A.D. Unfortunately this beautifully painted capstone was destroyed in a fire at the plantation house at Chichén Itzá in 1922.

6. An extensive treatment of the shift of the positions of the days in the Maya months will be found in Morley (1920:512–524) and *Year Book* 17 [Chapter 1.6 this volume]. As there pointed out, this shift does not appear to have taken place until toward the close of the New Empire. Indeed the very day when it may have occurred may be commemorated on rings of the Ball Court at Uxmal, as having been 11.15.16.12.14, 10 Ix 17 Pop, 1277 A.D.

7. This lahuntun ending itself fell only two days before another Maya New Year's Day, viz. 11.2.10.0.2, 3 Ik 0 Pop, the single intervening day being; 11.2.10.0.1, 2 Imix 4 Uayeb.

8. Dr. A. M. Tozzer has recently suggested that, when this lintel was re-used in the Temple of the Initial Series at Old Chichén Itzá, it was utilized not as a lintel but simply as a wall-stone. There is much in support of this contention. The earliest photograph of the Temple of the Initial Series shows this lintel on the ground partly in front of the front doorway. The second drums of the pair of Atlantean columns, which are supposed to have supported it, were found at the base of the pyramid and since this lintel was not found *in situ* on top of these columns, there is at least as much evidence that it had formed part of the wall, as that it had been the lintel over the front doorway. No other stone slabs were found which could have been the lintels for the north and south doorways, which would rather indicate that in cases of the other two doorways, at least, the lintels had been of wood.

No arch-stones have ever been found around this building, and it appears highly probable that it had a flat roof like those seen at Tulum. This fact alone fixes the Temple of the Initial Series as very late, and it appears more than probable that Dr. Tozzer is correct in suggesting that this lintel may never have stood over the front doorway of the

temple, but that it may have formed part of its walls instead. However, whether it served as a door-lintel or simply as a plain wall-stone matters little, since in either case it was a reused element as employed in the Temple of the Initial Series, and its original position is unknown.

9. In a final classification of the stones from the Temple of the Warriors, showing fragments of the mural frescoes, Mrs. Morris listed 80 as of sufficient excellence for use as museum specimens; 400 as showing features of minor importance, and thus of greater service to the specialist than to the general public; and 170 as too fragmentary to be of further use.

10. Dr. Morley has discussed this question of the colonization of Yucatán and the first settlement of Chichén Itzá by groups proceeding from the Old Empire region northward along the east coast of the peninsula by way of Chetumal Bay, Tulúm and Cobá, in a recent article (Morley 1927), and it is not improbable that Yaxuná may be the last link in the chain connecting Chichén Itzá with the Old Empire habitat.

I.15.

SYLVANUS G. MORLEY

Archaeology

YB 27:287–293, 1928

There were two principal investigations in Middle American Archaeological Research in 1928 as follows: 1. The Chichén Itzá Project; and, 2. The Uaxactún Project.

Two subsidiary expeditions were also made, one from Chichén Itzá, Yucatán, Mexico, and the other from Belize, British Honduras: 3. The Ek Balam Expedition; and, 4. The Pusilhá Expedition.

The Chichén Itzá Project completed its fifth field season on June 2 with the conclusion of excavation and repairs at the Temple of the Warriors.

The staff for 1928 consisted of Sylvanus G. Morley, in charge; Karl Ruppert, administrative assistant; E. H. Morris, archaeologist in charge of excavations; P. S. Martin, assistant archaeologist; Jean Charlot, Mrs. E. H. Morris and Lowell Houser, artists; Thomas R. Johnson, surveyor and draftsman; Miss Kathryn MacKay, housekeeper and trained nurse; Miss N. E. Piatt, secretary and bookkeeper; Gustav Strömsvik, carpenter; and Ira Guillot, mechanic.

On December 26, Dr. Morley delivered a lecture entitled "Recent Excavations of the Carnegie Institu-

tion of Washington at Chichén Itzá, Yucatán, and at Uaxactún in Guatemala," at the opening General Session of the American Association for the Advancement of Science at Nashville, TN, in place of Dr. L. H. Bailey, the retiring President, who was prevented by illness from giving the customary principal address; and on January 6, another lecture, at Mexico City, entitled "The Excavations of the Carnegie Institution of Washington in 1927 at Chichén Itzá, the Holy City of the Mayas," under the auspices of Dr. J. M. Puig y Casauranc, the Minister of Public Education.

Mr. Morris with most of the other staff members reached Yucatán on January 3 by way of New Orleans, and work on the Temple of the Warriors was resumed on January 11.

Excavations at Chichén Itzá during the 1928 field season were carried on at two centers: the Group of the Thousand Columns and the Temple of the Two Lintels at Old Chichén Itzá; work being done at five stations as follows: Temple of the Warriors (Station 4); The Northwest Colonnade (Station 10); The North Colonnade (Station 8); The West Colonnade (Station 9); and, Temple of the Two Lintels (Station 7), Old Chichén Itzá.

Again, as in 1927, the principal center investigation at Chichén Itzá was again the Temple of the Warriors and contiguous structures, the North, West, and Northwest Colonnades. The current year witnessed the completion of excavation and repair work at the Temple of the Warriors, and the preparation of the final report thereupon. Special reports covering different phases of this work by E. H. Morris, Jean Charlot and Mrs. Morris will be found in *Year Book 27* [Chapters 38.15 and 38.17 this volume].

Easily the outstanding event of the year at Chichén Itzá was the discovery on March 6 by E. H. Morris, of a turquoise mosaic disk in a sealed stone urn, buried beneath the floor of the sanctuary of the Temple of the Chac Mool, the earlier temple enclosed by and incorporated in the pyramid supporting the later Temple of the Warriors. This is probably the most important single object ever found *in situ* in the Maya area.

This magnificent specimen, 8.75 inches [22.2 cm] in diameter and comprising more than 3,000 pieces of cut and polished turquoise, was unfortunately in very poor condition when found, owing to the decay of the wooden plaque to which the elements of the mosaic had been fastened, and highly skilled technical attention was immediately necessary if it were to be preserved. The President of the Institution recommended to the Executive Committee an additional allotment to meet this emergency, and through the cooperation of Dr. Clark Wissler, Curator of the Department of Anthropology at the American Museum of Natural History, New York City, the services of Mr. Schouchi

Ichikawa, the Museum's most skilled preparator, were secured. Mr. Ichikawa reached Chichén Itzá on April 12 and, in addition to resetting the mosaic on a new base, he painted a water color reproduction of it for use in the forthcoming report upon the Temple of the Warriors. He returned to New York on June 11.

The President of the Institution and Dr. A. V. Kidder, Associate in charge of investigations in Early American History, visited Chichén Itzá from, March 1 to 12.

On March 10 exercises were held at the Temple of the Warriors marking a stage in the development of the Institution's archaeological program at Chichén Itzá. A special train from Mérida brought the Governor, Dr. Alvaro Torre Diaz, General Federico Verlanga, Chief of Military Operations in the State of Yucatán, and other prominent, officials. There were addresses by Dr. Merriam, Governor Torre Diaz, Mr. Eduardo Martínez Cantón, Inspector of Archaeological Monuments for the State of Yucatán, who had been designated the special representative of the Department of Archaeology of the Ministry of Public Education for the occasion, and Dr. Morley. A luncheon was served to 60 invited guests on the corridor of the *Casa Principal*, and the day closed, with a *baile regional*, or native dance, in which some 200 Maya Indians and Yucatecans from the neighboring villages of Pisté, Xochenpich and Dzitas took part.

Before leaving Yucatán, Dr. Merriam, accompanied by Mr. J. Reygadas Vertiz, the Director of Archaeology, Messrs. Eduardo Noguera and Eduardo Martínez Cantón of the Department of Archaeology, Dr. Kidder and Dr. Morley, visited Uxmal, where the Mexican government has carrying on urgently needed repairs at the House of the Governor.

On March 15, Doctors Merriam, Kidder and Morley left Progreso for Mexico City, where several days were passed in conferences with the Minister of Public Education, and other officials.

The practically complete restoration of the Temple of the Two Lintels at Old Chichén Itzá under the direction of Paul Martin was brought to a successful termination on April 28. The excavation and repair of this structure was commenced last year, and its esthetic as well as scientific importance [Chapter 1.14 this volume] indicated the advisability of complete restoration. Although the roof and most of the exterior walls had collapsed, practically all of the building stones were either lying where they had fallen, or were found built into later dry-laid walls in the immediate vicinity. A single section of the rear façade was standing to within two courses of its original height, and furnished the pattern for the arrangement of the elements of the design. The combination of these several factors made possible practically a complete restoration of this beautiful example of Maya architecture, even to the reconstruction

of the corbel arched roof, the first attempt of this kind ever made. While the cost in time of technical supervision, as well as in money, and the comparative scarcity of architectural units, where complete restoration may be carried out with such a high degree of accuracy, render it inadvisable, as indeed it is unnecessary, to do much work of this kind; nevertheless, the various operations involved in rebuilding this temple from the ground up, and the replacement of the decorative elements in their original positions in the façades have shed much light on ancient Maya architectural practices.

In addition to these more intensive investigations, involving excavation and repair, it has been thought advisable to carry on simultaneously further exploration of the outlying sections of Chichén Itzá, which stretch in some directions, particularly to the southeast, south and southwest, for several miles beyond the religious and civic center of the city. This work has been in charge of Karl Ruppert and has had most gratifying results. At least 12 groups of major importance were discovered, distant from half a mile to two miles [0.8–3.2 km] from the center of the city; several containing hitherto unknown types of buildings. The most important single construction found was a walled enclosure, 50 feet square. The wall surrounding this, although much demolished, had originally stood about 8 feet high, and was 4.26 feet in thickness. The enclosure has never been roofed and the only entrance is a doorway, 8 feet wide, in the middle of the north side. This doorway had had its jambs carved with panels of hieroglyphs, three columns of 19 glyphs each, 27 in each panel, or 54 in all. Notwithstanding the fact that all these glyphs are practically in perfect condition, no calendric or chronological signs, have been identified, and it has been impossible to date this interesting construction.

An extension of this exploratory work, specifically as applied to securing approximate ground-plans of structures without excavation, other than few pits to expose a wall or develop a corner, has led to most satisfactory results. The Market Place, an imposing construction, 245 feet [74.7 m] long and 22 feet [6.7 m] in depth, occupying the entire south side of the Court of the Columns, has been fairly accurately measured and plans have been laid for its excavation and repair. It was a matter of surprise that such accurate ground plans could be secured without extensive excavations, and application of this technique to other structures is recommended. Indeed further exploration of the outlying sections of the city must be made. As yet no single construction of the first period of the city's history, 531 to 669 A.D., has been identified, the single dated object there from being the re-used door lintel in the Temple of the Initial Series at Old Chichén Itzá. Perhaps a dozen buildings are surely referable, on stylistic grounds, as

well as because of the dates actually inscribed upon their door lintels, to the second period, 965 to 1191 A.D. While there are literally several hundred constructions temples, colonnades, ball-courts, domiciliary buildings, quadrangles, towers, platforms, causeways, etc., which may be ascribed to the third and closing period, 1191 to 1445 A.D., until now, not a single building has been found which is surely referable to the earliest, period. Exploration should be extended even beyond the limits of the city, as far as Yaxuná¹ for example, and even farther if necessary, in order to locate if possible the earliest Chichén Itzá and establish the site of the original city of this name.

A fourth activity at Chichén Itzá during the current season has been Miss MacKay's clinical work among the Maya Indians of the region. Free weekly clinics have been held, not only at Chichén Itzá but also at the neighboring villages of Pisté and Xochenchich, from which the labor of the Project is almost exclusively derived. These clinics were well attended. Simple talks on sanitation, and on the extermination of flies and mosquitoes were given, and the natives eagerly absorbed the information imparted. Miss MacKay finds the commonest illnesses from which the Maya of the region suffer are malaria-present rather in chronic than malignant form intestinal and digestive disorders, colds, anemia, and malnutrition. A continuous diet of corn, beans, salt pork, very little fresh meat and practically no green vegetables, probably causes most of their maladies, and malaria and its sequela are responsible for the rest. Bad colds and catarrhal affections are common and develop frequently into bronchial pneumonia and pleurisy, running extremely high temperatures, but in spite of this susceptibility to infections of the respiratory system there is almost no tuberculosis. The number of cases examined at the staff quarters during the current season was in the neighborhood of 250, many walking more than 25 miles [40.2 km] for treatment. Some 130 cases were treated at the clinics in outside villages, and 18 cases at the Mexican Government quarters at Chichén Itzá a total of about 400.

On March 25, Dr. Kidder and Dr. Morley and Dr. G. C. Vaillant of the American Museum of Natural History left Mexico City for Guatemala City. During the course of a fortnight's stay in Guatemala, Dr. Kidder and Dr. Vaillant visited some sites near, Lake Atitlán, in company with Dr. S. K. Lothrop of the Museum of the American Indian, Heye Foundation; later spent two days with Dr. Morley at Quiriguá. In Guatemala City several calls were made upon Mr. J. A. Villacorta C., Minister of Public Education, and the Institution's program of archaeological investigations in the Middle American field was considered with him. On March 30 Dr. Morley gave a lecture in Spanish be-

fore the Society of Geography and History of Guatemala, of which he is an Honorary Member, on the work of the Institution both at Chichén Itzá and at Uaxactún. On April 13, Doctors Kidder, Morley and Vaillant left Puerto Barrios, Guatemala, for Belize, British Honduras; and on April 15, Mr. Amsden, in charge of the Uaxactún Project, met them at Belize and took them up the Belize River to the head of navigation, and thence by mule-train to Uaxactún, 50 miles [80.5 km] westward in the northern central part of the Department of Petén, Guatemala.

The most important contribution at Uaxactún during the current season was the excavation of Pyramid E-VII, the key structure of the astronomically significant Group E. The discovery of a stucco mask buried under an outer covering of rough masonry and crumbling plaster was reported last year [Chapter 1.14], and during the present season three-fourths of this later and much cruder outer layer was removed, the remaining quarter, the southwest corner, being left as found for a control section. There stood revealed what is unquestionably one of the finest examples of ancient American architecture extant, a terraced pyramid with stairways on all four sides, two pairs of great stucco masks flanking each stairway. The summit had never supported a masonry superstructure, as the original and unbroken plaster floor clearly shows.

This buried pyramid must have been constructed at a very early date. Dr. Vaillant's excavations in the floor of the plaza of Group E, and around the foundations of Stelae 18, 19 and 20, the first two of which date from 97 A.D., clearly show that these monuments were erected subsequent to the latest floor level, which was in turn associated with the rough masonry covering, which had been built around Pyramid E-VII.

Stylistically considered, this stucco-covered pyramid is pre-Mayan. Its decorative motives are like nothing else known in the Old Empire region. They have a flavor of the Archaic, without being of the Archaic. Esthetically they are pre-Maya, but not necessarily un-Mayan. At the very early date when this pyramid was constructed, probably well before the beginning of Baktun 9, it is strongly to be doubted that Maya art and architecture had developed the essential qualities which became so diagnostically characteristic of it in later Old Empire times.

Dr. Vaillant's excavations in the plaza of Group E satisfactorily substantiate the indications afforded by the stylistic evidence. He found three earlier plastered floor levels below the last floor level, and 8 feet of debris between this last floor and the undisturbed humus soil. This debris was filled with potsherds, ash and small anthropomorphic figurines of baked clay, including two whistles, one modeled like the head of a man, the other a bat. Some of these clay figurines

strongly resemble similar Archaic figurines from the highlands of Guatemala and, without being identical, suggest some as yet undetermined relationship therewith, possibly not remote. Indeed the scientific importance of the results at Uaxactún this season lies in the possibility that the stratified meeting-ground of the Archaic and Maya cultures, so long sought, may at last have been found in this very group.

Aside from its indubitable scientific significance, which may have a fundamental bearing on the relative ages of the Archaic and Maya horizons, Pyramid E-VII is, esthetically considered, scarcely of less importance. Buried beneath a subsequent construction at a very early date, it has been preserved for us, 98 percent as it was 18 or more centuries ago. Of extraordinarily satisfying proportions and harmonious silhouette, this pyramid rises in dazzling silver-white brilliance against the somber green background of the Petén forest and the vivid cloud-flecked blue of the Petén skies, an architectural masterpiece of rare beauty.

While at Uaxactún, Dr. Morley visited Tikal for the purpose of examining the plain stelae in the northern part of the city. Opportunity was also taken to check his new reading of Stela 18, that is, 8.19.0.0.0. Stylistically considered, Stela 18 is the earliest monument at Tikal, indeed its only other stylistic analogues known anywhere being Stelae 9, 18, and 19 at Uaxactún, and Stela 1 at Uolantún, all dating from before the beginning of Baktun 9. The inscription unfortunately is not only fragmentary but also extremely weathered; the uinal and kin coefficients appear to be 0, and the day of the Initial Series terminal date is pretty surely 10 Ahau. If the tun coefficient is also 0, as is probable, then the only reading within the limits fixed by the stylistic criteria is 8.19.0.0.0 10, Ahau 13 Kayab. A new plain stela (D8) and a beautifully sculptured altar (II) accompanying it were found in front of the stairway leading to Temple III; another plain stela (D9) was found 100 yards [91.4 m] north of the northwest corner of the pyramid supporting Temple III.

Dr. Kidder and Dr. Morley returned to Belize on April 30, and the former returned to the United States on May 5. On May 2, Dr. Morley left Belize for Punta Gorda to visit a site named Pusilhá in southern British Honduras, about a mile [1.6 km] east of the western boundary of the Colony. Dr. Morley left Belize on May 12 and reached Chichén Itzá again on May 24, after an absence of two and a half months.

Mr. Martin returned to the United States on May 9, Mr. Ichikawa on June 11, Mr. and Mrs. Morris and Miss Piatt on June 12, Messrs. Strömsvik and Houser on June 14, Miss MacKay to Mexico City on June 1, and Mr. Charlot to Mexico City on June 16.

At the invitation of the Rotary Club of Mérida, Dr. Morley gave an illustrated lecture in Spanish at the

Peón Contreras Theatre in Mérida of the evening of July 3, describing the results of the 1928 field season at Uaxactún and at Chichén Itzá. The turquoise mosaic disk was on exhibition in the foyer of the theatre after the lecture and also at the newly inaugurated Casa del Pueblo, or People's House, during the evening of July 2. Dr. Morley left for Mexico City on July 4.

On July 7, Dr. Morley delivered to Professor Moise Saenz, the Under-Secretary of Public Education, the turquoise mosaic disk, the stone urn in which it was found, and the associated material, a carved jadeite pendant, two jadeite beads and a conjuring stone of the same material.²

At the invitation of Dr. Alfredo Pruneda, Rector of the University of Mexico, Dr. Morley gave three lectures before the Summer School of the University as follows: July 9. Origin of the Maya Civilization, and the Old Maya Empire; July 11. Decline of the Maya Civilization and the New Maya Empire; and July 13. Maya Hieroglyphic Writing.

He returned to the United States on July 14.

The appointment of Mr. Ruppert as administrative assistant of the Chichén Itzá Project has relieved Dr. Morley of the routine of administration at Chichén Itzá, and his time has been devoted to the preparation of his report on the *Inscriptions of Petén*. As originally contemplated in 1914 this work was to have contained "descriptions and decipherments of all known Maya texts, which will be so arranged as to be a ready and standard book of reference on Maya chronology" (YB 14). It soon became apparent, however, that further field work would be necessary before such a book could be written (YB 14), and as early as 1915 so many texts had been transcribed at Copán alone (YB 15), that it was decided to bring out the Copán texts in a volume by themselves. The World War intervened just as the first chapter of this book had gone to press (YB 16), and the first volume of this work (Morley 1920) was not published until the spring of 1920 (YB 19).

During Dr. Morley's seven trips to the Department of Petén in 1914, 1915, 1916, 1920, 1921, 1922, and 1928 (YB 14, 15, 19, 20, 21) he has collected material for the second volume of this work on the Maya inscriptions, to be entitled *The Inscriptions of Petén*, and he is now engaged upon its preparation.

NOTES

1. Yaxuná is located about 15 miles [24.1 km] south and slightly west of Chichén Itzá, and is the western terminus of the Cobá-Yaxuná *sacbe* or highway (YB 26).

2. When this ball of jadeite was first shown to the Maya laborers, they unanimously identified it as a *sastún* or conjuring stone, which the ancient Maya priests are said to have used in malting incantations.

SYLVANUS G. MORLEY

Archaeology

YB 28:299–301, 1929

The two principal investigations in Middle American Archaeological Research, the Chichén Itzá Project and the Uaxactún Project, completed their sixth and fourth seasons, respectively, during the current year. As in former years, subsidiary expeditions were sent out to other sites, one to the Old Empire city of Piedras Negras in the northwestern corner of the Department of Petén Guatemala, the other to the New Empire center at Macanxoc-Cobá in northeastern Yucatán, Mexico.

The staff for 1929 consisted of the following members: At Chichén Itzá, Sylvanus G. Morley, Associate in charge; J. O. Kilmartin, engineer and administrative assistant; Karl Ruppert, archaeologist in charge of excavations; H.E.D. Pollock, assistant archaeologist; Miss Katheryn I. MacKay, housekeeper and trained nurse; Miss Bess L. Holbrook, secretary and bookkeeper; A. J. Kerr, mechanic; at Uaxactún: O. G. Ricketson, Jr., in charge; A. L. Smith, assistant archaeologist, Mrs. O. G. Ricketson, Jr., and E. Shufeldt, field assistants; and in Washington, E. H. Morris, archaeologist; Mrs. E. H. Morris and Jean Charlot, artists, who were engaged in preparation of the final report upon the excavation of the Temple of the Warriors. In the group at Chichén Itzá there should be included the personnel of the Yucatán Medical Expedition of the Department of Tropical Medicine, School of Public Health, Harvard University: G. O. Shattuck, director; J. C. Bequaert, entomologist; J. Sandground, helminthologist; K. Goodner, bacteriologist; and B. L. Bennett, laboratory technician.

Dr. Morley reached Mexico City on January 1, and after conferences with Lic. Ezequiel Padilla, the new Minister of Public Education, and Mr. José Reygadas y Vertiz, the Director of Archaeology, proceeded to Yucatán. The other members of the staff reached Yucatán on December 31, by way of New Orleans, and work was resumed at the Caracol, or Astronomical Observatory, on January 23. Pursuant to the policy of commencing no new unit of excavation until work already under way should be completed and published, excavations at Chichén Itzá during the current season were restricted to the Caracol (Station 5), study of which was begun in 1925, continued in 1926 and 1927, but suspended in 1928, and supplementary studies at the Casa Redonda (Station 15).

The most important discovery at the Caracol during the current season was the finding of an earlier

circular substructure, buried within the upper, rectangular platform, from which the tower proper rises. This circular substructure is in perfect condition, still retaining its original plaster finish, but as yet no stairway has been found connected with it, by which access could have been gained to the tower on the summit. This discovery has made necessary further excavation, in order to determine the constructional details involved, as well as extensive repairs to preserve and at the same time expose the buried substructure, so that another season's work will be required to complete the study and repair of this architectural unit. Another major activity at Chichén Itzá during 1929 was a continuation of the survey of the site by J. O. Kilmartin, Assistant Topographical Engineer, U. S. Geological Survey. In 1923, Mr. Kilmartin surveyed the central area comprising the larger and better-known architectural units, using a scale of 1:200,000 and 5 foot [1.5 m] contour intervals. This year an even larger tract (nearly a mile square) lying immediately south and southwest of the central area was surveyed, and all constructions noted thereupon. The same scale and contour interval were employed in each case, and it is proposed to republish the two maps as one. Several important and previously unreported architectural groups were located by this survey and a number of stone causeways were found connecting them, the most important being the one running from the Monjas in the middle city to the Group of the Hieroglyphic Lintels at the south end, almost a mile [1.6 km] in length.

A third major activity at Chichén Itzá during the present year was the medical survey of the surrounding region by the Yucatán Medical Expedition of the Department of Tropical Medicine, School of Public Health, Harvard University, under Dr. G. C. Shattuck, undertaken as a cooperative project with the Carnegie Institution. Three different groups of Maya and mixed-bloods were examined: 1. The laborers at Chichén Itzá, largely drawn from the neighboring villages of Pisté and Kaúa; 2. The inhabitants of Dzitas, the nearest railway point to Chichén Itzá; and 3. The inhabitants of Chan Kom, an Indian village lying 14 miles [22.5 km] southeast of Chichén Itzá. Surveyed maps of the last two villages were made by Mr. Kilmartin, giving location of houses, wells, latrines, corrals, pigsties, etc. Vital statistics, sanitary conditions and prevalent diseases were tabulated for all three groups, and blood and fecal specimens secured from several hundred individuals. The most surprising feature of the survey seems to be the almost complete absence among the Maya either of syphilis or the probably related yaws so prevalent in other tropical countries.

A fourth activity at Chichén Itzá during the current season was the free clinic conducted by Miss

MacKay. The clinic is now in its third year and has been steadily growing; 624 cases were treated at Chichén Itzá, Pisté, Xochenpich, Dzitas, Kaúa, Yulá, Nictchá and Chan Kom this year, in some cases patients walking as far as 30 miles [48.3 km] for treatment. Medicines are distributed *gratis*, and this feature of the Project, so ably conducted by Miss MacKay, has had an important part in creating the very friendly relations existing between the Indians of the surrounding region and the members of the Institution's staff at Chichén Itzá.

Excavations were closed at Chichén Itzá on June 15, and the members of the staff returned to the United States shortly thereafter, Dr. Morley and Messrs. Kilmartin, Ruppert, and Pollock by way of Mexico City; Miss Holbrook and Mr. Kerr by way of New Orleans. Miss MacKay returned to her home in Mexico City.

Through the courtesy of Dr. E. L. Hewett, Director of the School of American Research and the Museum of New Mexico, Dr. Morley has occupied offices in the Palace of the Governors, at Santa Fe, New Mexico, for the past three years. Summer quarters were opened here on July 1, and Dr. Morley, Messrs. Kilmartin and Ruppert, and Miss Holbrook spent parts of the summer and fall there. Mr. Kerr returned to Chichén Itzá, to take care of the hacienda early in August.

1.17.

SYLVANUS G. MORLEY

Report on the General Status of Middle American Archaeological Research

YB 28:329–333, 1929

The moment is perhaps not inopportune to review briefly the general status of Middle American archaeological research, and to indicate promising lines for early investigation.

The Institution has maintained for the past six years two principal centers of study in the Maya area, one at the Old Empire site of Uaxactún, in northern Guatemala, the other at the New Empire site of Chichén Itzá, in northeastern Yucatán, Mexico. Since the former is the oldest Maya city yet known, on the basis of the dated remains and since Chichén Itzá was easily the most important city of the New Empire, and especially, since the excavations of the past six years have yielded

results of great, not to say fundamental scientific importance at each, it appears advisable that investigations should be continued at these two centers.

The Government of Mexico, in addition to very considerable excavation projects just north of the Maya area (that is, in central Mexico), and extensive explorations in the extreme southern part of the Republic, has carried on excavation and repair work at both Chichén Itzá and Uxmal in the northern Maya region.

The British Museum and the Field Museum of Natural History have excavated at various sites in western and southern British Honduras during the past three years, Lubaantún, Pusilhá, Hatzcap Ceel, Cahal Pichik, etc. The foregoing about exhaust the list of major excavation projects in the Maya field during the past six years.

During this same period there have been several expeditions, more exploratory in nature, which have visited the region, for different purposes, in behalf of other scientific institutions.

Tulane University has had two expeditions in the field, in 1927 and again in 1928, which visited the little-known southwestern part of the area, bringing back a large amount of new material, ethnological, linguistic, geographical, climatological, as well as archaeological, especially from the highlands of Guatemala and southern Mexico.

The Field Museum of Natural History, in addition to its archaeological investigations, has carried on ethnological studies, not only at various points in British Honduras, but also in the highlands of Guatemala; considerable vestiges of the ancient culture were found, myths, traditions, prayers, etc., which indicate that further work along these lines would yield important results.

The Peabody Museum of Harvard University has had expeditions in southern Mexico (Veracruz coast plain), Guatemala (highlands), and Honduras (Ulloa [Ulúa] Valley) which have shed light upon these outlying, but strategically important, and, certainly culturally, related areas.

The Museum of the American Indian, Heye Foundation, has sent several expeditions to Guatemala, which have brought back valuable archaeological and ethnological collections. This institution has laid special emphasis on the region south of the Maya field, especially Costa Rica, from which it probably has the largest ceramic collection in the world.

The American Museum of Natural History has confined its investigations more particularly to the highlands of central Mexico, where much progress has been made in classifying the complex but fundamentally important ceramic types of that region.

Finally, the Government of Guatemala, through the quasi-governmental Sociedad de Geografía é

Historia has published a series of illustrated pamphlets on the archaeological sites of the republic, written in a popular vein, for the public schools, which has aroused widespread interest in the archaeology of the country.

In addition to the foregoing activities of governmental and institutional agencies, Middle American archaeological research has profited during the past six years by the investigations of several independent students. The fundamental studies of Dr. John E. Teeple on the Maya hieroglyphic writing merit special mention in this group. He has proved conclusively that Glyphs D and E of the Supplementary Series indicate in each case the age of the moon number of days since new moon on the date of the corresponding Initial Series. In order to bring Dr. Teeple's work into closer relation with that of Dr. Morley, in the same field, the former has, recently been appointed a Research Associate of the Institution.

The translations of Post-Conquest Maya manuscripts by Ralph Roys and those of Nahuatl manuscripts of the same period by B. L. Whorf are outstanding contributions to the study of Early American History.

During the past six years more than half a hundred investigators in archaeology, ethnology, physical anthropology, linguistics and history, representing a dozen different scientific agencies, governmental as well as private, have carried on studies in the Maya field, and a very considerable amount of information and material has been accumulated.

Expeditions involving enormous personal effort, prodigious hardship and costing, in the aggregate, hundreds of thousands of dollars have been carried through to brilliant conclusions. Many gaps in the body of existing knowledge have been filled many blind spots in the picture of ancient Maya times have been painted in. The ground, it would seem, has been sufficiently covered for a restatement, a closer definition of the major problems of Middle American archaeological research, and the way cleared for a general attack.

It appears to the writer that the most pressing need of the moment is the organization of an informal Committee on Mayan Research, composed of members from the different institutions actively engaged in carrying on investigations in this field.

Some of the duties of such a committee would appear to be: 1. A careful re-examination of the results of previous investigations, and, in the light of these data, a restatement of the major research problems presented; 2. The organization of future investigations in such a way as to avoid duplication of effort; 3. The allocation of research problems and areas of exploration to the institutions and individuals best equipped to handle them, so that the maximum efficiency in research may be secured and, at the same time, concerted and correlated attacks made at the most strategic points; 4. Fi-

nally, the establishment of a system of interchange, of results, even of personnel in special cases, so that each problem may be served by the specialist best fitted to cope with it, and all institutions and individuals have the immediate advantage of the latest results of all investigations.

Such a condition as the foregoing is not a scientific Utopia impossible of achievement; rather, it would be the almost certain resultant of the formation of such a committee. Closer cooperation, direction of research, freer interchange of material and personnel would inevitably result in swifter and more effective solution of the problems presented, and a clearer picture of the ancient Mayan contribution to the development of mankind—the ultimate goal.

The specific problems suggested are some of those which the writer believes should receive priority of attention; they do not include, however, any outside the field of anthropology, important as are some of the allied problems in geology, climatology, biology, epidemiology, etc.

1. GENERAL PROJECTS

1. A survey of the Maya linguistic stock, especially along philological lines. This is recommended particularly as offering a proven means of approach for establishing the sequence in the separation of the various dialectic groups from the parent stock, and the reconstruction of the parent language.

2. A survey of Maya architecture. The frequent association of dated monuments with architectural remains, to say nothing of dated lintels, steps, jambs, cornices, wall-panels, etc., gives support to the belief that an extensive comparative study of all known Maya buildings would establish their chronological sequence, and would permit the relative dating of otherwise undateable buildings by means of stylistic criteria such as type of ground-plan, façade decoration, roof-ornamentation, etc.

3. A survey of Maya ceramics. The enormous bulk of Maya ceramic material, the complexity of wares, and multiplicity of shapes and designs, its occasional association with definitely dated monuments, and its very general occurrence at dated sites, render it extremely probable, if not indeed certain, that an extensive comparative study would establish the definite chronologic sequence of the various wares found, as well as their foci of distribution, and time relations with extra-Maya ceramic types.

4. The compilation of a Maya hieroglyphic dictionary. It is now possible to decipher the meanings of about one-third of the individual glyphs, and the publication of all known examples of certain signs will soon be feasible.

5. A translation and publication of post-Conquest Mayan and Nahuatl manuscripts. There exists a not inconsiderable body of unpublished and untranslated manuscript material, written in the Maya and Nahuatl languages with the characters of the Spanish script. As these manuscripts constitute practically the only documentary source for the ancient history of Middle America, their complete translation and publication has become a pressing need. Fortunately, in spite of the highly specialized character of this work, there are a few students' sufficiently equipped to undertake it.

2. SPECIFIC EXPLORATION PROJECTS

6. The exploration of southern Yucatán and northern Guatemala. This is one of the least explored areas in the Maya field, and is, at the same time, scientifically, the most important, since in this region are located the transitional sites between the Old and New Empires. Expeditions from the Peabody Museum of Harvard University have penetrated the northern part of this region, and expeditions from the Carnegie Institution have worked in from the south. There still remains, however, a large intermediate section which has never adequately been explored, and which should contain sites of the Transitional or Colonization Period, 460 to 690 A.D. circa.

7. The exploration of the region lying west of the Usumacinta River, more especially the southern part between the upper reaches of the Usumacinta and Chiapas Rivers, comprising the entire Lacantún Valley and the great forests to the north, sometimes called El Desierto. This is the eastern half of the State of Chiapas in Mexico. Expeditions from the Ministry of Agriculture of the Mexican government and from Tulane University have partially explored this region, but there are almost certainly unknown sites still hidden in these vast, practically trackless forests.

8. The exploration of the Territory of Quintana Roo, Mexico. The expeditions of the Carnegie Institution to the east coast of the Yucatán peninsula, and more recently to the Old Empire site of Macanxoc-Cobá, in northern Quintana Roo, have developed the fact that this region was occupied as early as the Early Period of the Old Empire. A network of stone causeways traverse the section, and it is confidently anticipated that further exploration will bring to light other dated sites.

3. SPECIFIC EXCAVATION PROJECTS

9. The excavation of some site in the southern Veracruz coast plain. This region is the no man's land between the Maya and Nahuatl cultures, a meeting ground which has been strongly influenced by each. From this region comes the famous Tuxtla Statuette,

the earliest dated object in the Maya hieroglyphic writing, 98 BC circa. Recent expeditions from the Peabody Museum of Harvard University have discovered highly important transitional material here.

10. The excavation of some western Old Empire site, preferably on the Usumacinta River. The east, north and south sections of the Old Empire have had considerable excavation, going-back more than 40 years, but the west has been entirely neglected. An intensive excavation project in the Usumacinta Valley, where Maya art attained its most brilliant, development, is greatly needed.

11. The excavation of some western New Empire site, preferably in the State of Campeche, Mexico. The archaeological remains of the eastern half of the Yucatán peninsula are much better known than those of the western half, and yet, the early explorations of Teobert Maler in this region and the more recent expeditions of the Ministry of Public Education of the Mexican Government and of the Carnegie Institution clearly indicate its archaeological importance. The selection of a type site for intensive study would shed much light on the archaeology of this little known region, and at the same time supplement excavations now being carried on elsewhere in the Yucatán peninsula.

12. The excavation of some site in the highlands of Guatemala. In ancient times the Pacific coast plain of Guatemala was a main thoroughfare for north and south migrations. Along this great natural highway, the only feasible land route between North and South America, there must have been constant shift of population in very early times. Some of these groups penetrated the highlands of Guatemala and occupied different parts of the high central valleys. Here, perhaps, next to Uaxactún, is the most likely place to find the meeting ground of the Archaic and Maya cultures. The establishment of the relationship between these two great composite cultural groups would constitute one of the most fundamental contributions that could be made to the field of Middle American archaeology.

1.18.

ALFRED V. KIDDER

Division of Historical Research

YB 29:91-119, 1930

This Division, which was created by Act of the Board of Trustees of the Institution in December 1929, com-

prises a Section of Early American History, a Section of Modern American History, and a Section of the History of Science. Working in collaboration with one or other of the Sections are certain investigators from other institutions. The Division has both administrative and coordinative functions. As an administrative unit it serves those groups within the Institution which are engaged in the study of man's history, in the broadest sense of that word. In its less formal capacity it is designed to promote intercourse between the Institution's workers in the humanistic field; to direct attention to and integrate research upon problems which are of fundamental importance for all students of man's career, but which, are too complex and too ramified for successful attack by any single specialized discipline; and, finally, it aims to facilitate cooperation between the Sections and other scientific agencies.

The present report is devoted largely to the work of the Section of Early American History because the problems of that group have been such as to require particularly careful consideration during the past year. They also well exemplify the type of coordinated research which the Division hopes to sponsor.

SECTION OF EARLY AMERICAN HISTORY

In designating the group engaged in studies of the pre-Columbian career of the American Indians, the term history has been used as symbolic of a desire to do away with the somewhat rigid distinction, which has generally been drawn between archaeology and history. The work of the Section is, of course, archaeological in that it deals with material remains rather than with written records. But archaeologists seek to gather from ruined buildings and potsherds the same sort of knowledge that historians derive from books and manuscripts, and while the subject matter and, therefore, the primary methods of the two disciplines are naturally unlike, their ultimate aims are identical, for both archaeology and history strive to recover and to interpret the story of man's past. Archaeology, however, has all too generally been prosecuted as if the excavation of specimens were an end in itself. Antiquities have, as a rule, been collected more for their rarity or, their beauty than for what they might tell of the doings and the thoughts of the human beings who made them. Emphasis in archaeology is gradually shifting, however, from things to what things mean; and archaeological finds are fortunately coming more and more to be considered as historical documents.

In its work in the Maya field of Middle America and in Southwestern United States, the Section is exceptionally well placed to aid in further development of the modern conception of archaeological research. The Maya represent perhaps the highest peak of Na-

tive American civilization; the ancient Southwesterners were laying the foundations of communal agricultural existence. Each people, therefore, illustrate a most significant stage in human progress. And their remains cover such long periods of time and embrace such remarkable growths of culture that they force upon the student a keen realization of the deep perspectives of history. Finally, the problems raised by excavation, both in the Maya country and in the Southwest, are so obviously insoluble without help from many other branches of science, that the archaeologist is impressed by the very necessary truth that his work is merely one small part of the single great investigation of man's evolution.

MAYA STUDIES

The Maya, as has been intimated, were the most brilliant people of the aboriginal New World. Their civilization had its roots in the primitive farming culture, which originated well before the birth of Christ, somewhere in the Middle American highlands or in the Andean region, and which through ramification and diffusion ultimately gave birth to all the higher pre-Columbian developments in the Western Hemisphere. The Maya, whose earliest known remains lie in the forested plains at the base of the Yucatán peninsula, took over or brought with them from the highlands the elements of this primitive culture: corn growing, pottery making and presumably also the rudiments of their later artistic, religious and social systems. In the low country they flourished like a tropical flower. Their glyph-recorded history begins at about the time of Christ (according to Dr. Morley's correlation of Maya and Christian chronology), but before then they must already have spent many centuries in perfecting the material arts, and particularly the extraordinary astronomical and calendrical knowledge of which we find them possessed even at that remote period. The great epoch of Maya history, the Old Empire, saw the building of Tikal, Copán and many other magnificent and temple-adorned cities. The causes for the eventual break-up of the Old Empire are as yet unknown, but decay it did, and the formerly populous southern region reverted to jungle. The Maya, however, had already been pushing northward into Yucatán, and there, during the New Empire at such cities as Chichén Itzá and Uxmal, they enjoyed a remarkable renaissance. Ultimately they fell under dominance of the rising Nahuatl powers of Central Mexico and, at the time of the Conquest, were once more undergoing a period of decadence. What would have happened if the Spanish had not come; whether they would again have rallied and pushed on to still further heights; or whether they, like the ancient Greeks, whom in many ways they

so closely resembled, had finally expended all vital and creative energy, are questions of more than merely academic interest, for the Maya still form the bulk of the population of Yucatán and of Guatemala, and the future of those countries therefore depends to a large degree upon the ability of these Indians to receive European culture, to adapt it to their needs and to develop it in such a way as to permit them to play a worthy role in the modern world.

Even so brief a resumé indicates the importance of research upon the Maya. To the New World historian it is naturally of paramount significance, for the Maya were leaders in the cultural development of Middle America, influencing directly or indirectly all other groups in that entire area. The Maya, too, were the only people who consistently and accurately recorded dates, thus providing a starting point from which to work out the chronology of all the other high pre-Columbian cultures. For the student of more general problems, the Maya also provide invaluable data. Their history involves the rise, spread, efflorescence and decline of an agricultural civilization. It gives splendid opportunities for evaluating the influence of those racial and environmental factors which have been, so potent in shaping the destinies of all peoples, but whose action has been so little understood.

Carnegie Institution entered the Maya field in 1914 when Dr. S. G. Morley was appointed Research Associate. The activities of Dr. Morley and his staff fall into sequent periods of exploration and excavation.

The soundest method for attacking any archaeological problem is to conduct a preliminary survey of the area concerned in order to determine the general distribution of its remains, to sense the broader aspects of historical trends, to identify the lines of evidence which will best repay close study, and finally to select for intensive excavation the key sites which, will yield the fullest information upon the customs and the career of the people who are being studied. Pursuing the above principles, Dr. Morley devoted approximately 10 years to exploring the Maya area from end to end. He visited practically all previously known sites and discovered many new ones, the most important being Uaxactún, Xultún and Naachtún. Accounts of his very difficult journeys may be found in the *Year Books* of the Institution. Their result was a much more definite knowledge than had hitherto existed of the territory occupied by the Maya at different periods of their career; and an evaluation, based on the abundance and quality of remains, of the significance of each of those periods. In other words, a definite historical outline was achieved. Dates, hieroglyphically inscribed, formed the primary evidence for Dr. Morley's determinations. At the same time by deciphering cryptic inscriptions and by finding and reading many new

ones, he much more than doubled the known number of these invaluable glyphic time-markers.

For intensive excavation were selected Chichén Itzá in northern Yucatán, Mexico, and Uaxactún in the Department of the Petén, Guatemala; reconnaissance digging was also to be done at Tayasal on Lake Petén Itzá. These three sites cover the entire range of Maya history: Uaxactún is, on the basis of recorded dates, the oldest Maya city; Chichén Itzá was founded before the abandonment of Uaxactún and was occupied until shortly before the coming of the Spaniards; Tayasal, the last independent stronghold of the Maya, did not fall until the close of the seventeenth century.

THE UAXACTÚN PROJECT

From the time of its discovery in 1916, Dr. Morley felt that Uaxactún merited thorough investigation. It was not only the oldest Maya city known, but its inscriptions indicated that it had been inhabited for upwards of 5.5 centuries. It gave promise, therefore, of throwing light on the whole period of the Old Empire, and he believed it possible that it might even yield data upon the formative stages of Maya culture. Uaxactún was surveyed and mapped for the Institution by Mr. Frans Blom in 1923. In 1925 a contract was entered into with the Government of Guatemala for a 5-year project, with privilege of renewal; and in the same year the Institution's work there began under direction of Mr. Ricketson. Five field-seasons have now been devoted to excavations. They have centered about one of the large temple-surrounded plazas of the city, attention having originally been directed to this particular quarter by the fact that certain of its monuments and buildings gave evidence of being so placed as to produce lines of sight of astronomical significance. The question as to whether or not Plaza E was in reality an observatory involves complex and still unsolved problems of Maya astronomy and the Maya calendrical system. But the excavations of Mr. Ricketson, undertaken to establish the exact orientation of building units thought to be involved in the observatory complex, have produced purely archaeological data of the greatest interest and importance. The western side of the plaza was fronted by a large pyramid, worn by time and the inroads of the jungle to a peaked mass of crumbling stone. Work on its eastern face, in an attempt to locate remains of a stairway, disclosed underneath the debris a grotesquely modeled mask of heroic proportions, which further digging showed to be part of the adornment of an earlier structure, entirely covered by and embalmed in perfect preservation within the later pyramid. To bring it fully to light required part of the season of 1927 and the entire season of 1928, when it stood revealed as a beautifully proportioned truncated

pyramid, its flat top approached by four stairways flanked by series of great masks. Its terminal platform bore no temple, and it therefore seems likely that it served in itself as a huge altar, or elevated place for holding important ceremonies.

The construction is lime stucco over a core of crude masonry. Had it not been sealed in and protected from the elements, the plaster shell, including the stairways and masks, would quickly have disintegrated. Such has, indeed, apparently been the fate of all unprotected early Maya buildings. This example, therefore, stands as our only illustration of the architecture of its period. It differs strongly from anything heretofore known, but it exhibits an astonishing sophistication of line and mass, a feeling for the subtleties of contour and the play of light and shade, which can only be interpreted as the result of long practice in the designing and erection of this type of structure. It is certainly very old. Its exact age still remains to be determined, and for this purpose Mr. Ricketson is making studies of the levels of the plaza fronting it and of their relation to dated stelae.

As soon as the pyramid was cleared it was realized that most careful record must be made of its appearance, for it could not be expected long to withstand the ravages of a tropical climate and the inevitable encroachments of the jungle. It was photographed in the large and in all detail, planned and sectioned in every aspect. The mapping was a most difficult task, for the thing was, so to speak, a gigantic piece of sculpture, no two of its lines being parallel, no two angles the same. But from the data brought back it has been possible during the present year for Mr. S. J. Guernsey to prepare an accurate model which will be shown for the first time at the annual exhibit of the Institution in December 1930.

When the buried pyramid had been uncovered, pits were sunk in front of it which showed that, old as it doubtless is, there exist below it and also under the plaza to the east deposits of even greater antiquity, consisting of layers of refuse, presumably village debris, which contain abundant fragments of pottery and figurines distinctly un-Maya, as that term is generally understood, but obviously resembling the so-called archaic remains of the Guatemala highlands. This was a discovery of the very greatest value. Up to 1928, when the find was made, no definite evidence was in our possession for connecting the Maya civilization with the early cultures from which it was theoretically supposed to have sprung. But here, lying directly below the most ancient known specimen of Maya architecture, itself presumably dating from the very first part of the Old Empire, were materials in undoubted stratigraphic position because sealed in by subsequent constructions, which will make it possible to judge the

quality of the transition between the ancestral plateau culture and that of the nascent Maya.

Because of the great importance of the remains beneath the plaza, the seasons of 1929 and 1930 were devoted to a painstaking dissection of the underlying strata. It proved to be a heart-breaking complex undertaking as the whole place was leaved and inter-leaved with floor levels and living surfaces, each one of which had to be followed to its ultimate termination over or under or against some unit of construction or some significant bed of debris. Much was learned as to the habits of the Maya city planners in the laying out of their temple-surrounded courts. The large collections of pottery, clay figurines and other artifacts from the different levels have now been moved to Guatemala City, where they are under study by Mr. and Mrs. Ricketson and Mr. Smith.

While the plaza excavations were going on, Smith carried out a series of detailed studies on the relation between dated monuments and plaza floors in an attempt to determine their chronological relation to the buildings near them. As result, he believes that stelae were at least occasionally moved from the position of their original erection. The investigation ties in very closely with that of Dr. Morley on the growth, and meaning of Maya ceremonial centers. Another research by Mr. Smith concerned itself with the density of population within the city limits, so to speak, of Uaxactún. The work was based upon a careful count of the house mounds in a surveyed area and estimates of the number of persons per family. Several unknown quantities are naturally involved; such as the likelihood that not all the houses represented by the mounds were occupied at the same time, but his general conclusion is that the immediate vicinity of the temple groups was very thickly populated.

Dr. Morley's selection of Uaxactún for excavation has already amply been justified, but it is a question whether or not work at so inaccessible a site should go forward indefinitely. It lies in the heart of the Petén jungle. Supplies and staff must be transported from the coast up the shallow and winding Belize River in dugout canoes towed by motor launches, a journey of from two days upward, depending on the stage of the water. From the head of navigation at El Cayo, four days on mule-back over very bad trails are required to make the 55 miles [88.5 km] to Uaxactún. There the water supply is extremely precarious. Added to such difficulties are swarms of insects and a debilitating tropical climate. Hence the cost, both in money and in human effort, of excavating at Uaxactún is necessarily extremely heavy, and while the city still has without question much to yield, it is possible that the work already done has skimmed the cream, as it were, from the site; and it might perhaps in the long run be more

efficient to postpone further investigation until such time as the inevitable opening up of the country will render work there more easy of accomplishment.

The check-up of the Uaxactún results now being made by Mr. Ricketson and his staff should go far toward answering the question. Should it be decided to go elsewhere, two obvious follow-ups present themselves. On the one hand, it would be of great value to excavate in the highlands in order to collect archaic material for comparison with the subplaza pottery and figurines, thus approaching the problem of origins from the lower end; on the other, one might attempt to trace the Old Empire culture, as made known by the excavations at Uaxactún, northward and eastward into the peninsula of Yucatán. At all events, work will be continued until the deposits and structures now under investigation have been completed. Decision must also depend upon the development, during the next few years, of the Section's general program, and upon the plans of other agencies in the Maya field.

THE CHICHÉN ITZÁ PROJECT

Its outstanding importance in the New Empire and, indeed, until very shortly before the Spanish Conquest, induced Dr. Morley to select Chichén Itzá as the site for the major effort of the Institution's campaign of excavation. The city was founded before the close of the Old Empire, and can therefore be expected to throw light on the earliest developmental phases of the New. During the latter period it was a leader both politically and ceremonially. Better than any other, it illustrates the influence of the Nahua cultures, of Mexico upon the Yucatecan Maya. It contains more hieroglyphic inscriptions than any of the late centers. The great length of its occupancy gives opportunity for determination, on the sound basis of stratigraphic observation, of the trends of artistic and material development through many centuries. Its remains are abundant, culturally significant and well preserved. And, finally, it possesses the practical advantages of accessibility, abundant labor supply and healthful climate. Under contract with the Government of Mexico, which from the beginning has been consistently and effectively helpful, excavations were started in 1924 and have continued to date.

The Chichén Itzá project has differed from most archaeological undertakings in the New World in that from its inception Dr. Morley has striven for three definite objectives over and above the usual single one of recovering specimens and information. These may be stated as follows: to conduct the work in a manner calculated to create a feeling of confidence by the Mexican government and people in the good faith of foreign scientific agencies; to handle the site in such a

way as to make it a permanent record of the artistic achievement of the Maya; and to develop Chichén Itzá as a focal point for correlated researches.

The first of the above mentioned extra-archaeological objectives is that of fostering international scientific good will. In some ways this is the most important, single aspect of the Institution's work in Middle America; it certainly has been the least understood. To make clear the situation which the Institution is attempting to do its bit to remedy, it is necessary to revert to the statement made at the beginning of the Section report that the older archaeology considered the acquirement of specimens an end in itself. The retarding effect of this upon the development of archaeology as a science need not here be discussed beyond saying that for many years it kept archaeology at about the intellectual level of stamp collecting. Its practical results have been almost equally disastrous. For over a century there has been a steady flow of artistic and antiquarian treasures from the countries of their origin to museums of a few of the larger and richer nations. Much that would otherwise have been lost has of course thus been saved for posterity. But the smaller countries are now coming to appreciate the historic and educational value of such materials, while foreign museums still wish to carry on in the traditional Lord Elgin manner. There has accordingly been a world-wide tightening of laws governing excavation and in many regions it is now impossible for an outside agency to prosecute any archaeological work whatever, while in others it can be done only under conditions regarding disposition of specimens which are so confiscatory that backing for expeditions can not be procured.

The situation as it exists today is very bad and is growing worse. It can only be rectified by concessions on both sides, which in turn must be the result of a new conception of the purpose of archaeological work and the meaning of archaeological materials. Foreign agencies should realize that the relics of a country's past not only belong rightfully to that country, but that in the long run they are most useful there, always granted that they are adequately protected and are at all times available for study. Foreign agencies should also realize that the primary purpose of their expeditions is study of the history of man rather than the amassing of collections. If these points of view be held they will naturally be content with a fair division of representative material and will not demand all. The home governments, on the other hand, while they are, of course, masters by possession of everything within their borders, should understand that prehistoric man was not bound by modern political limits, that his history is part of a common heritage, and that there is at least an ethical right for all mankind to profit from its

study. They should, moreover, take into consideration the fact that, both practically and intellectually, it is to their advantage that their antiquities be known in other lands.

For the purpose of helping to bring about such understandings Carnegie Institution of Washington, in its negotiations with governments and its prosecution of field investigations, has steadily striven to overcome the feeling that the entry of a foreign scientific agency necessarily means wholesale looting of archaeological remains. It has frankly stated its adherence to the proposition that title to all antiquities rests in the country of their origin. It has, therefore, exported nothing directly. But it has insisted upon proper care for the materials it has excavated. It has at the same time urged the great desirability of sending representative collections abroad and has recommended gifts by the countries concerned of certain specimens to leading museums. As result, the Mexican government has already placed in the national museums of England, Germany, Peru and the United States series of the beautiful painted stones which emanated from the Temple of the Chac Mool. Although the Institution would not advocate the exportation of unique type material or unduplicable objects of pre-eminent importance, it hopes that governments of countries in which it works will continue to deposit specimens from its excavations in such outside institutions as can best profit by them.

The attitude of the Institution has rather generally been misunderstood. It has been felt that because it supports no museum it can afford to work without acquiring collections, and that by so doing it has spoiled the field for those who must produce tangible results in objects for museum display. Persons taking this attitude have not realized that it would be infinitely easier for the Institution to remove the product of its excavations to the United States for study and for deposition in places accessible to its workers; or that by direct gifts to museums and by home exhibition of its more spectacular finds it could much more easily than is now the case secure financial backing for its projects. It is probable that, although the policy of the Institution may indeed make things difficult for agencies whose sole desire is to acquire collections, it will in the long run prove distinctly beneficial to those whose primary objective is recovery of historical information and which are willing to share equitably with countries whose ruins they investigate. It seems not unreasonable to believe that the satisfactory relations established between the American Museum of Natural History and the Government of Mexico, both for exploration and the exportation of materials, and the concession recently granted to the University of Pennsylvania by the Government of Guatemala for work at

Piedras Negras, have to some degree, been facilitated by the manner in which Carnegie Institution has carried on its own researches in those countries.

A second aim of Dr. Morley, in his administration of the Chichén Itzá project, has been so to handle the site as to make it an enduring monument to the genius of the ancient Maya. Chichén Itzá of all great Maya cities is the most accessible and the most healthy. And, with the possible exception of Uxmal, it is without a rival in the number, beauty and architectural distinction of its buildings; What Luxor is to Egypt, or Athens to Greece, Chichén Itzá is to Yucatán. A heavy responsibility, therefore, rests upon him who excavates there.

To derive bare archaeological facts would be simple enough. Plazas could be trenched, pyramids torn open and the still standing parts of ruined temples stripped of the mounds which now protect them. These undertakings would be speedy and relatively cheap. But they would pave the way for destruction by weather and vegetation which would very shortly reduce the city to a meaningless jumble of stone. Both the Mexican government and Carnegie Institution have appreciated from the beginning the necessity for care in digging and for leaving all cleared structures in shape to resist further deterioration. It has been a costly business, for it has necessitated time-consuming and expensive methods of reaching objectives and has also involved much strengthening and repair of structures in imminent danger of collapse and the replacement of fallen elements which, if left scattered on the ground, would be meaningless and would also be exposed to eventual destruction.

Preservation has not been the only concern. It has been desired that when cleared all buildings should be both understandable and beautiful. Comprehension of an ancient structure demands knowledge of its relation to others, of the methods employed in its erection, of alterations made during its occupancy, and of the factors responsible for the condition in which it was found when excavated. The mere uncovering of an architectural unit will therefore not suffice. Openings must be left to expose earlier remains; sometimes, as in the case of the Temple of the Warriors, large parts of deeply buried pre-existing buildings must be kept intact and rendered accessible. There should be opportunity to examine the interior, even of solid construction, to make plain the methods of the ancient mason. Careful planning permits details of wall and column, vault and roof to be easily seen and studied. And, as at the Caracol, where a section of a great fallen cornice has been held in the exact position of its devastating collapse, there may vividly be illustrated the tremendous forces of destruction.

Intelligent understanding of a building and of what it signifies is made possible by such practical

means. But subjective values must not be overlooked. Beauty, in detail and in mass, must be striven for intelligent restoration, no matter how accurate, destroys beauty. and so robs ancient structures of their most important psychological effect. The mere fact, of ruin induces realization of the inevitable and relentless erosion of time and brings the beholder to the proper frame of mind for grasping, the deeper significance of what he sees. Hence repair must not only be meticulously correct but must be limited to essentials and never be blatantly evident.

Different methods are required for each unit undertaken. Archaeological knowledge, engineering skill and a keen sense of esthetic values must go to produce the result which it is hoped ultimately to obtain. The cost has been and will continue to be great; but the obligation both in funds and in time is deliberately assumed. In the first place Chichén Itzá, because of its outstanding scientific and artistic importance, deserves our best efforts. Second, it is thought that if the project is handled in a manner so obviously altruistic it cannot fail to produce a feeling on the part of the Mexican government and the Mexican people that American agencies can be trusted within their borders; and, third, if Chichén Itzá can be kept both interesting and beautiful, it will without question become a Mecca of travel, and, incidentally, a most valuable asset, for archaeology which, like every other science, needs its show-windows. Its more recondite aims the public cannot, in the beginning, be expected to grasp; but public interest must be roused and eventual public understanding must be achieved if archaeology is to go forward; for from the public comes, in the last analysis, all support for scientific endeavor.

Adherence to the above policies shaped from the first the course of work at Chichén Itzá and dictated the selection for study of the Temple of the Warriors and the Caracol, the two principal buildings which have been excavated to date.

The Temple of the Warriors was chosen for first attack because it was the largest example of a type of late structure of which no well-preserved specimen remained, and so might be expected to yield architectural information not to be had from any standing temple in the city. It was also badly, apparently almost hopelessly, ruined, thus giving opportunity to find out what facts could be learned and what materials could be rescued from such a mound, of which literally hundreds exist at Chichén Itzá and other Yucatecan cities. Work at the Temple of the Warriors occupied the four seasons from 1924 to 1928 inclusive. Mr. Morris, who was in charge throughout, has transformed this most unpromising pile of stone into an impressive and lasting monument. Every phase of its long structural history has been elucidated, and every succes-

sive increment has been left in such condition as readily to be understandable by the visitor. The finds of sculpture and fresco were abundant beyond all expectation. The final report upon the Warriors by Mr. Morris and his collaborators is now in press.

A second major undertaking has been the excavation and repair of the Caracol, a building of unusual interest in that it is by far the finest and best preserved of the very few round structures in the Maya area, and because there are good grounds for believing it to have served as an astronomical observatory. The Caracol is a great circular tower surmounting a massive rectangular substructure. It possesses many unique architectural features—curved vault, central stem, spiral staircase, and tremendously heavy cornices both on the base and the tower. When work started, the Caracol resembled a jagged tooth of gray stonework protruding from heaped piles of fallen masonry which almost completely masked the contours of the lower part of the tower and of the platform. First attention was devoted to tying into place and so preserving the tottering remains at the top which contained all that was left of the supposed observational passages and their openings. Mr. Ricketson had charge of this greatly needed bit of salvage. The subsequent extensive clearing and rehabilitation have been carried out by Mr. Ruppert. The entire building has been freed of debris, the walls of the tower strengthened and all the great upper cornice replaced, except for a single section which has been left as it originally fell. The platform has proved a mine of information. First one and then a second earlier substructure have come to light, each circular and each enclosed in perfect preservation within later accretions.

Work on the Caracol proper was finished at the end of the present season, but the digging about its base has disclosed a maze of smaller ruins and plaza levels whose relations to it and to adjacent buildings will eventually have to be the subject of careful study. As it now stands, the Caracol, like the Temple of the Warriors, is both understandable and rarely beautiful. Progress reports on the excavations here, at the Temple of the Wall Panels, the Temple of the Lintels, the Temple of the Initial Series, the Temple of the Phalli, and upon the many other smaller undertakings carried on between 1924 and the present may be found in the *Year Books*.

With completion of the excavation and repair of the Temple of the Warriors and the Caracol, the first phase of the purely archaeological work of the Chichén Itzá Project has reached a satisfactory conclusion. There must now ensue a period of pause for the digestion and publication of results and the formulation of plans for the future. Digging, as is always the case has progressed more rapidly than study; and the preparation of reports, which are of course the ultimate and deter-

minative product of all scientific work, has lagged even further behind. The Temple of the Warriors volume is in press, but the Caracol has not yet been described; nor have 10 or more smaller excavated buildings, all of much interest and some of great importance, been treated save in summary articles in the *Year Book*. To get all this material into print and available to the archaeological world now becomes the principal task of the Chichén Itzá staff. The papers will be descriptive, but Dr. Morley plans to take advantage of their preparation to begin a thorough study of the details of Maya architecture as manifested at Chichén Itzá.

Information upon the gross aspects of architecture, such as the grouping, orientation, size, ground plan and ornamentation of structures, has been a natural product of the investigation; but close comparative scrutiny of the minutiae of building practice, the tricks, so to speak, of the mason's trade, has not yet been made; and there is every reason to suppose that intimate knowledge of them will provide an extremely significant criterion for further work.

To make the above statement clear it is necessary to say a word in regard to the handling of specific archaeological problems. To begin with, one is dealing with large amounts of undocumented and therefore, at first contact, updateable material which must be ordered chronologically before they can be interpreted in terms of cultural trends or historical events. To make headway with so great a mass, one must select, for preliminary study, certain phenomena or groups of objects which, more clearly or more easily than others, will serve to block out the investigation. These may be called preliminary criteria.

In the Maya field the best and most obvious criterion for determining the relative age of remains is supplied by the hieroglyphs, and Dr. Morley and other students of the Maya were of course prompt to seize upon and exploit this line of research. Their work upon the glyphs, as has already been said, has served to define the main currents of Maya history and to place in their relative order the principal groups of cities. The hieroglyphic record, however, is fragmentary and it has already been rather thoroughly searched. More dates will doubtless be found, but for further advance we must fill in the picture in greater detail; we must not only, assign to their proper period the many cities which contain no dates, but we must do the same for individual buildings in the cities, for their chronological ranking will supply us with knowledge of the age and therefore of the meaning of the things they contain.

Success depends upon intelligent selection of the above-mentioned preliminary criteria. The best clues are provided, by materials, which are abundant and easily acquired, which readily and accurately reflect cultural change, and which are of such a nature that

their chronological position, may readily be determined. Pottery most ideally, fulfills these requirements and ceramic study is now going forward actively. Pottery, however, not superficially common in the Maya region, and many years must elapse before enough excavation can be done to supply us with sufficient specimens for valid sequences covering all periods and all parts of the area. Manifestations of the graphic arts, particularly sculpture, are also, as Spinden has demonstrated, a highly useful means of working out chronologies, but much Maya sculpture was in stucco and has either perished or, if preserved, still awaits excavation, and stone stelae, bas-reliefs and carved ornaments are relatively rare. Our best criterion, at least at the present time, appears therefore to be the details of architecture. The Maya were incredibly diligent builders; the mere act of building would, in fact, appear to have been an integral part of their very coercive religious system. Maya buildings are therefore abundant, and although most of them are in an extreme state of dilapidation, careful study, as has often been proved, will reveal much precise information as to cornices and moldings, stone-cutting and laying, vault construction, frescos, bas-reliefs, etc. Such features are, by and large, probably the most easily studied manifestations of Maya culture; and, because of the frequent additions that the Maya made to their structures, because of their habit of piling platform on platform and temple on temple, it should not be difficult to determine the chronological relations of much material; and to establish, on the sure basis of stratigraphic evidence, the principal trends of architectural development. Dr. Morley, in his conduct of the excavations at Chichén Itzá, has accordingly laid special stress upon the uncovering of buildings, and Mr. Ruppert and Mr. Pollock are now engaged in careful comparative studies of constructional and ornamental detail. When the architecture and art of Chichén Itzá are intimately known, the work will be extended to other cities of the late period in northern Yucatán, and eventually to the east coast and southward. To aid in the research, Mr. Bolles, a student of architecture with experience in the Gothic and Near Eastern fields, has been added to the staff for the coming year.

The studies of buildings will beyond question prove of great value. But they must be accompanied and supplemented by investigation of other categories of material, of which pottery is by far the most important. The usefulness of pottery as an archaeological criterion needs no stressing. It has again and again shown itself to be the single most reliable and most accurate means for establishing the sequence of cultural periods. The prehistory of Egypt, of the Near East, of the American Southwest, of the Valley of Mexico, has been, or is being, outlined on the basis of

ceramic evidence. The reason for this, as has often been pointed out, lies in the plasticity of the potters' art and in the fragility of its products, the former quality permitting constant change, the latter insuring both opportunity for modification and abundance of remains in the form of sherds.

Research upon Maya pottery presents many difficulties. To begin with, the mere acquiring of material is a slow and arduous process. Potsherds, so common and so easily collected from the surface in and regions where the ground surrounding ancient sites is bare, are, in the Maya country, hidden by tangled undergrowth. Even when, after clearing, the earth is laid bare, the fragments are all too often found to be rotted by the corrosive acids of jungle humus. Hence usable specimens must be sought by slow and expensive excavation. Another difficulty is caused by the fact that the Maya had advanced to that stage of development where vessels for everyday use were turned out wholesale and were either undecorated or ornamented conventionally. Fine pieces were, of course, also made, and the evidence provided by these is more easily read; but they are rare, and the run of sherds, the great body of material with which the ceramicist must necessarily deal, can only tell its story after there have been worked out very unobtrusive changes in clay and finish, and very subtle differences in vessel shapes. Lastly, there seem to be several major divisions of Maya ceramics, perhaps of differing origin, certainly more or less independent in development. Some of them are allied to one non-Maya group, some to another, others have no readily perceived affiliations. For their ultimate comprehension there will be required an extremely wide comparative knowledge of Central American pottery from the earliest times onward. So bafflingly complex and yet so urgently necessary a research can not successfully be prosecuted as a sideline of excavation; it demands the best energies of specialists. In this capacity, Mr. H. B. Roberts has joined the staff of the Section.

Ceramic work for the Institution was started in 1926 by Dr. George C. Vaillant, who, on the basis of materials then available from the excavations at Chichén Itzá and of collections in Yucatán and the United States, made a basic classification of the wares of northern Yucatán. He was also able, as result of excavations in the courtyard of the Temple of the Phalli, to suggest a chronological sequence for the majority of the types established by his classification. Continuance of the research was prevented by Dr. Vaillant undertaking, for the American Museum of Natural History, a study of the immensely important archaic remains of the Valley of Mexico, but he has kept intimate touch with the Institution's program; he carried on the first stratigraphic excavations at Uaxactún in

1928; and during the past winter he came to Yucatán to confer with Mr. Roberts upon, the development of the latter's investigations.

Mr. Roberts began his work by reviewing thoroughly with Dr. Vaillant the collections in storage at field headquarters. He then searched for places at Chichén Itzá where rubbish would most likely have accumulated, selecting for trial excavation the deep depression of a dead cenote, or natural sink-hole, which lies close to the Monjas and several other important buildings. In the bottom of the cenote there was located and sectioned with trenches a deposit of from 7 to 12 feet [2.1–3.7 m] in depth. The strata were not always clearly marked, but it was possible to determine four certain and three probable layers of superimposition, and to collect, from them a large amount of sherd material for type studies and statistical analysis.

Although the data have not as yet been thoroughly digested, certain important results are already apparent. The dead cenotes were repositories for rubbish; the deposits in them accumulated with sufficient slowness to insure their reliability in determining sequence of wares and styles; and the tentative classification worked out by Dr. Vaillant has been proved valid.

Both Dr. Vaillant and Mr. Roberts believe that the objectives of future work should be specific rather than general. The subject is an enormous one. Museum materials are scanty and, as a rule, poorly identified as to place of origin. Dr. Vaillant has already derived about as much information as can now be gathered from study of existing collections, and his conclusions, although unpublished, have most generously been placed at Mr. Roberts' disposal. They therefore advocate a series of intensive field investigations in certain regions which appear to have been centers of pottery development. Stratigraphic excavation at sites in such areas should provide both new data and a knowledge of the sequence of styles which will render understandable many now practically valueless museum specimens. Northern Yucatán is recommended for prior consideration and Chichén Itzá as point of first attack, thus permitting close correlation between the ceramic, architectural and other researches. In addition to excavation, Mr. Roberts will continue studies begun in 1930 of local clays, and of modern Yucatecan methods of pottery making. He hopes also to supplement observation of the more obvious characteristics of ancient and modern pottery by chemical and microscopic analyses similar to those used with such success in South America by Dr. Linné of Sweden.

Dr. Morley's work on the hieroglyphs has progressed steadily; the second section of his compendious presentation of all known dated monuments is approaching completion. The first, under the title *The Inscriptions at Copán*, appeared in 1920. The present

book covers the Petén; and the third number of the trilogy will include the dates from the rest of the Maya area. These volumes contain exhaustive analytical and comparative descriptions of texts and discussion of their bearing upon all aspects of Maya history. The fact that they also bring together the entire corpus of data now available gives them rank as prime sources for all future work in the field of Maya epigraphy.

Closely allied with Dr. Morley's work is that of Dr. John Teeple on the hieroglyphic inscriptions. For the past two years Dr. Teeple has been a Research Associate of the Institution in Middle American Archaeology and the results of his studies have been published during the current year under title of *Maya Astronomy* (Teeple 1931). He has shown conclusively that lunar phenomena form a large part of the record in the Maya inscriptions and that the age of the moon, that is, distance from the new moon at any given moment, was always a matter of great importance. The different methods of numbering the lunar months, while at first numerous, suddenly crystallized in 9.12.15.0.0 of the Maya Chronological Era (428 AD in Dr. Morley's correlation of Maya and Christian chronology) into a uniform system which was used throughout the Old Empire. Seventy years later astronomer-priests at the city of Copán discovered the eclipse syzygy, and from this time on, one by one the cities of the Old Empire gradually fell away from the Uniform System, each adopting a system of its own, which resulted in general confusion. Important as are Dr. Teeple's contributions to the more restricted field of Maya astronomy, they are already overshadowed by their larger historical implications, as indicating the diverse cultural elements at work within the Old Empire. It is confidently to be anticipated that further investigations along the same line will shed additional light on the Old Empire period, the Golden Age of the Maya civilization.

An offshoot of the Chichén Itzá project has been the exploration of Cobá, a ruined city in the eastern part of northern Yucatán. Cobá was heard of by the American explorer, John L. Stephens, in 1841, but was not visited by him. Later, presumably in the 1890s, Teobert Maler was at Cobá, as is evidenced by some photographs by him of its buildings preserved in the museum at Mérida. He made no report, however, and the actual opening up of the city was only accomplished in 1925, when Dr. Morley organized a series of expeditions for its exploration and study. These proved Cobá to have been not only a very large and important center in late times, but to contain hieroglyphic inscriptions indicating its occupancy at an unexpectedly early period of the Old Empire. Further work, therefore, promises to throw light on the whole problem of the colonization of Yucatán from the Petén, and data may well be recovered upon the still very imperfectly

understood era between the break-up of the Old Empire and the Renaissance.

Mr. Eric Thompson, of the Field Museum, who as a member of the Chichén Itzá staff took part in the 1925 expeditions, offered during his vacation in the winter of 1930 to conduct new explorations for the Institution at Cobá. With Mr. Pollock he spent several weeks there. Materials for a map were gathered, architecture was studied, and particular attention was devoted to a remarkable series of paved roads or causeways which radiate from Cobá in all directions.

Mr. Thompson reports as salient discoveries a number of carved and plain stelae, several: new causeways, three of which were found to have actually crossed Lake Macanxoc, and two ball-courts of Old Empire type with sloping walls, but provided with stone rings, an interesting link between Old and New Empire courts.

The architecture of Cobá presents problems difficult of solution. There are many similarities to the Old Empire cities of northern Petén, but in some respects, notably the length and width of the rooms, certain of the structures are in advance of those of Petén. In addition, there are several buildings which undoubtedly belong to the late East Coast or Tulúm style.

Mr. Thompson believes that Cobá, as a possible link between the cities of northern Petén on the one hand and Chichén Itzá and other sites of northwest Yucatán on the other, demands investigation. Comparative studies of pottery and of architecture would appear to offer the readiest means of approach to the problem. At a moderate cost it should not be difficult to obtain information on the pottery types, and possibly their sequence, at Cobá; and at the same time clear up certain outstanding architectural puzzles. Such work should be possible without large expense for plant, as it would not involve extensive excavation. Buildings need only be investigated sufficiently to settle definite architectural points, and no great outlay on repair would be required. Seaplanes, once the trees at the end of Lake Cobá had been cut down, should prove the best means of transport.

Mr. Thompson believes that when Cobá has yielded its quota of information on ceramics and architecture, Yaxuná, the terminus of the great causeway which runs westward from Cobá, could be carefully worked. This city was undoubtedly closely connected with Cobá both culturally and commercially, but it is only a scant 12 miles [19.3 km] from Chichén Itzá. Some of the masonry of collapsed structures appears to be of early Cobá type, yet the only standing structure is built in the same style as the Monjas at Chichén Itzá. At Yaxuná, then, we should find Cobá ceramics, possibly merging into Chichén Itzá types, or even directly associated with Chichén Itzá types in circumstances that

would permit the Cobá wares to be linked chronologically with those of Chichén Itzá on the one hand and with those of Petén on the other. In such manner, certain Chichén Itzá potteries might be dated in terms of the Old Empire. This in turn would facilitate isolation of pure Maya types, and so place us in better position to decide what elements at Chichén Itzá are attributable to Mexican influence and what are due to the merging of Maya and Nahua cultures.

Mention has been made of reconnaissance digging at Tayasal on Lake Petén Itzá, the last independent Maya stronghold. During the field seasons of 1921 and 1922, Dr. Guthe, under an agreement with the Government of Guatemala, carried on excavations for the Institution at this site.

After the abandonment of Chichén Itzá about the middle of the fifteenth century, according to the early chroniclers, the Itzá, migrated southward from Yucatán and established their capital at Tayasal on the shores of Lake Petén Itzá. The immediate object of Dr. Guthe's excavations was to ascertain whether proof of direct contact could be established from the material culture. Two distinct periods of occupation were traced: the earlier giving back to Old Empire times and probably contemporaneous with other sites on the shores of the Lake Flores and Ixlú for example which flourished at the very close of the Old Empire, and the later Itzá reoccupation of the fifteenth, sixteenth and seventeenth centuries. While further work will have to be done at Tayasal before its connection with Chichén Itzá can be established by means of the excavated material, satisfactory corroboration of the Spanish descriptions of Tayasal at the time of the Conquest (1697) was obtained, and this project should be continued.

An important event of the year was Colonel Charles A. Lindbergh's cooperation with the Institution for reconnaissance of archaeological areas by airplane. Becoming interested as result of observation of ruins in Yucatán during flights made early in 1929, Colonel Lindbergh offered his assistance to the Institution, and during the summer, at President Merriam's suggestion, he spent several days at the chairman's archaeological camp at Pecos, New Mexico, making flights over the Canyon de Chelly, the Hopi country, Chaco Canyon, and the Pajarito Plateau. The photographs of ruins and of topographic features secured at that time by Colonel and Mrs. Lindbergh demonstrated the great utility of the airplane as an agency for locating sites, and for determining their relation to water supply and arable land.

While Colonel Lindbergh was in New Mexico he discussed with the chairman the possibility of air exploration in the Maya country, and in October 1929, through the good offices of Pan American Airways, which supplied the plane and furnished ground fa-

cilities, five days flying were carried out over British Honduras, Yucatán, Mexico, and the Department of the Petén, Guatemala. The primary purpose of the undertaking was to ascertain how much information as to a heavily forested region could be gathered from the air. The Central American jungles are so dense that not only is ground travel exceedingly slow and difficult, but ruins, even of largest cities, often remain unknown even when well-traveled trails pass in their immediate neighborhood. Furthermore, it is almost impossible from the ground to get any proper idea of the country one is traversing because one is literally so engulfed in vegetation that distant views can never be obtained. Hence we have lacked much archaeologically significant information as to the topography of the Maya area, its relief, its drainage systems and the distribution of swamp, savanna, and forest.

The flights took place from Belize, British Honduras, Mrs. Lindbergh acting as photographer, Mr. Ricketson and the chairman alternating as observers. The first day's flight led up the Belize River to El Cayo, thence to the ruins of Tikal whose high temples, standing clear of the jungle, served as orientation point for setting a northward course. Tikal to Uaxactún, a hard day's trip on mule-back, was made in six minutes. While over the latter place, photographs were taken of the Institution's camp and the ruins. North of Uaxactún and south of the Yucatecan settlements lies a long stretch of uninhabited and mostly unexplored forest. This was crossed, the party spending the night at Mérida. The following day, Colonel Lindbergh headed eastward to Chichén Itzá for photographs, then turned south and flew down the interior of the peninsula to Belize. The third day, Tikal and Uaxactún were revisited, a stop was made on Lake Petén Itzá, and the afternoon was devoted to a flight across the little known country behind the Cockscomb Mountains. On the fourth day there was explored the hinterland of the Yucatán east coast; and the morning of the fifth gave opportunity for study of the Cobá district.

Results were most satisfactory. Several hitherto unrecorded ruins were observed. It was found that after a little practice one was able to distinguish the mounds of the larger cities, even when they were covered with the heaviest sort of jungle. It was also possible to locate them with a fair degree of precision by such natural landmarks and, compass bearings as would enable ground parties to reach them with much less difficulty than if they were "going blind." Most important of all, it became clear that not only major geographic features, but the details of forest-type distribution can readily be made out and plotted from the air. As different sorts of vegetation reflect varying soil conditions and rainfall, and as the latter factors were naturally of great importance in determining the re-

gions best suited for occupancy by an agricultural race, such as the Maya, it may readily be seen how much valuable knowledge could quickly be gathered by an intensive air survey. Also, in prosecution of biological, geological and other investigations the plane would be of much service in transporting small parties to the interior where they could be landed on lakes or the larger rivers. It is hoped that the Institution may be able in the not too distant future to avail itself of this method of carrying forward its work in the Maya country.

Exploration by land or in the air, hieroglyphic research, excavation, the study of architecture and of pottery, all these activities are purely archaeological. No matter how carefully planned or how successfully carried out, they can only result in the attainment of limited objectives. For with the best of methods archaeology can recover no more than the bare skeleton of the past; a skeleton, too, which is both fragmentary and disarticulate.

The archaeologist in the field is primarily a fact-finder. In this he needs no help. When, however, he comes to interpret his discoveries, when he attempts to say what ruins and potsherds mean, he requires knowledge of all the multitudinous factors which through the ages have conditioned human existence and shaped human action. His case is like that of the paleontologist who would clothe with life the crushed bones from the fossil quarry. And, as does the paleontologist, he must infer from the effect that present environments and present happenings have on contemporary organisms, what he can of the action of similar phenomena in the past.

The archaeologist is thus abruptly hailed from the comforting shade of his trenches to the glare of the existing world, and there he stands bewildered. He surveys the environment of today to find that its complexities are utterly beyond his power to comprehend. He looks at the very simplest of modern peoples; their life proves unbelievably involved. But if he be willing to face the situation and not pop mole-like back into his burrow, he will find that other sciences are grappling with the problems of plants and animals, of weather and rocks, of living men and existing social orders; collecting, classifying, winnowing detail, and gradually formulating the basic laws which render this perplexing universe understandable. Beside them and with them the archaeologist must work if his results are to be more than the putterings of the antiquary.

All this is obvious enough; but surprisingly seldom have archaeologists made serious attempts to ally themselves with other scientific men. Dr. Morley from the beginning has realized that the unraveling of Maya history demands such cooperation. Hence his insistence that the work in Yucatán should become the nucleus of a group of correlated researches, and that

Chichén Itzá should be their first focal point. To make clear the bearings of studies now under way and to indicate what others should be added, it is necessary to list the outstanding categories of information that are needed.

In the first place, we should work from the present, which we know or can know, back to the as yet unknown past. Thus we are forced to examine the Maya of today, their physical structure, their psychology, their social and economic life, their language. We can also learn much of their career during the past 400 years from study of the documentary history of Yucatán. Of conditions existing at the Conquest the earlier historical sources tell us many things. Passing from the Maya themselves to the environment which has, as with all people, been so potent a molding influence, we find that we need knowledge of the physiography and geology of Yucatán and of its climate; also of its flora and fauna.

The list of the archaeologist's requirements reads like the contents table of an outline of science. And rightly so, for no single constituent of the cosmos fails to bear, in one way or another, upon human life. Some lines of investigation, however, are naturally of greater, or at least of more immediate, importance than others; and work along some of them already has begun. In the short descriptions which follow, the collateral researches are considered from the point of view of what they may be expected to reveal, directly or by inference, as to the history of the Maya. Each one, however, has extremely important problems of its own, and each bears significant upon and meshes closely with all the others. Discussion of these interrelations can not be undertaken in this very general preliminary statement, both for lack of space and because it is believed that in future *Year Book* reports special studies can be handled more fully and more authoritatively by the men in actual charge of them.

The initial group of investigations concerns the living Maya, and logically first comes consideration of who and what the Maya are. These questions lie in the province of physical anthropology, the science which deals with the bodily structure of mankind. Answers are needed by the historian in order that he may judge of the origin of the Maya and of the degree of their relationship to other aborigines of Middle America. He wishes to know, for example, whether or not they are, closely allied, to the highland peoples from whom they seem to have derived the germs of their culture; whether they give evidence of racial homogeneity or of extensive crossing. Also, it is necessary to learn what admixture of Caucasian blood has taken place since the Conquest.

In 1927, Dr. George Williams, under joint auspices of Harvard University and Carnegie Institution, inaugurated the work by examining some 1,800 Yucatecans.

He also conducted tests in basal metabolism and collected blood samples. The results are now being prepared for the press. It is obvious that the investigation should continue, and arrangements have been made with the Institution's Department of Genetics for Dr. Morris Steggerda to visit Yucatán the coming winter. Dr. Steggerda will make a preliminary survey of the field. He will also check, by remeasurement of some of the individuals originally examined, the work of Dr. Williams, in order to make sure that the methods of the two researches are similar and that their results will therefore be comparable.

Closely related to the researches in physical anthropology are those in medicine. No final appraisal of the bodily make-up of a people can be made without knowledge of the factors which control their health. Their material and intellectual accomplishment are presumably largely dependent upon their physical condition. The findings of medicine are essential for the study of modern social and economic conditions in Yucatán. Their value for the historical investigation, although less obvious, is also very great. It has, for example, been suggested by Spinden that the fall of the Old Empire may have been brought about by the wasting effect of endemic-yellow fever. Whether or not this was the case must be settled by medical evidence. And even if this devastating diseases should prove not to have been present in the New World in pre-Spanish times, other maladies, either virulent, such as syphilis, or subtle as are nutritional troubles, may have exercised deep influence upon the career of the Maya. Malaria, now the most harmful of all tropical diseases, may also have been present. To settle such points the archaeologist, historian must, have the cooperation of the student of medicine.

The original step in studying the health conditions of the modern Maya was the establishment at Chichén Itzá of a free clinic under the able direction of Miss Katherine MacKay, which for several years has served the towns supplying the project's workmen and which has come to be visited by Indians from all the surrounding country. The records of the clinic have provided a foundation for continued observation, and the friendly feeling inculcated among the natives has been of inestimable value in facilitating subsequent investigations, not only in medicine but in all lines requiring cooperation of the natives. The health survey of Yucatán was inaugurated in 1929 under joint auspices of the Department of Tropical Medicine of the School of Public Health of Harvard University and Carnegie Institution. It is under the direction of Dr. George C. Shattuck. Two winter seasons have been spent by Dr. Shattuck and his staff in the field.

They have made clinical examinations, have gathered statistics and have conducted specific studies of

certain prevalent diseases. They have found the country, for the tropics, unusually healthy, but intestinal and respiratory troubles prove to be extremely common. Yucatán, according to Dr. Shattuck, is admirable territory for studying the very important and little understood tropical anemias, because malaria which as a rule is so abundant and the symptoms of which overlie and becloud the more subtle manifestations of anemia in other regions, is here relatively rare and its effects can, in a general sense, be factored out. As a first step in this investigation, Dr. Shattuck has undertaken the determination of normal standards, to be followed by nutritional research, checks of the bacillary and amebic dysenteries and of other pertinent factors. Extension of the work will lead to consideration of the whole question of life in the tropics, involving the human geography of all tropical countries and the ability of various peoples to exist under conditions of heat and humidity. There are naturally involved matters of race, of climate, of food supply, of native and introduced diseases and of the physical properties of the sun and the atmosphere. So important does Dr. Shattuck regard this extension of the research that he is planning to devote the coming winter to a general study of what has been done by other investigators and to conferences with physicists, climatologists and nutritionists, whose present advice is essential and whose future cooperation must presumably be called for.

During the 1930 season the principal objectives of study were the basal metabolism of Maya Indians, their blood pressures and their blood pictures with special reference to anemia. This work was done at Chichén Itzá. In Valladolid, the relative prevalence of syphilis among Maya Indians and Yucatecans was the main objective. Data on blood pressure, anemia, malaria and other diseases were likewise obtained. Dr. Shattuck also demonstrated to Dr. Francis I. Procter at Chichén Itzá some cases of a chronic folliculitis which closely resembled trachoma, and which may ultimately prove to be a form of that disease. Dr. Procter is an oculist of large experience who has been actively interested for some years in trachoma among the Indians of the Southwestern United States. His interest in this eye disease of Yucatán resulted in the examination of school children and others in a number of places near Chichén Itzá. and at Valladolid, with the result that it proved to be very prevalent.

The data collected by Dr. Shattuck and his associates in 1929 and 1930 will be more fully presented in a report now being prepared for publication. From the beginning of the Chichén Itzá project it has been realized that studies would have to be made upon the social and economic life of the Maya of Yucatán. Only with thorough knowledge of the living people and of

modern conditions can one utilize understandingly the documentary records of the post-Conquest period, and from them work still farther backward into prehistoric times. But like research in pottery, or physical anthropology, or medicine, the task of analyzing an existing population can not even be begun as a sideline or by-product of any other investigation. It requires special abilities and specialized methods. But particularly does it require that its development be shaped by a person of broad experience and wide interests, a man who can formulate and direct attacks upon the many concrete objective elements inherent in the social complex, without losing sight of the deeper meanings which are masked under surface intricacies. Dr. Robert Redfield of the Department of Anthropology of the University of Chicago has been appointed leader of the survey, the University very generously allowing the Institution to avail itself of, his services during a certain part of each year.

In 1930, Dr. Redfield spent three months in Yucatán. It was not the purpose of the trip to collect materials on any special ethnological topic or in any particular local community. He desired to take such a rapid general view as would permit him, first, to determine some of the problems suitable for study, and, second, to prepare a program of research. No systematic study was therefore made of the ethnology or folklore of the Maya, but sufficient information was secured to permit a judgment as to the character and range of culture in Yucatán. His time was about equally divided between the city and the country, between the civilization of Mérida and that of the villages. About three weeks were spent in Mérida. A trip was made to Hunucmá, in the northwestern part of Yucatán, and another to Sotutá and its environs, in the south central part. Because of the fact that Chichén Itzá was a convenient point of departure, and because the southeastern part of the state is changing more rapidly than other regions and is therefore more interesting, special attention was given to the Chichén Itzá district. Preliminary information was secured from the two villages most accessible to Chichén Itzá: Pisté and Xochenpich. About 10 days were spent in Chan Kom, south of Chichén Itzá. In Tekom contact was made with Filomeno Pat, Indian leader, who offered to help representatives of the Carnegie Institution in making contact with the uncivilized Maya of the Territory of Quintana Roo.

As result of his observations, Dr. Redfield proposes that there be made a well-rounded study leading to a description, of contemporary society in the peninsula. The inhabitants are not the representatives of a single simple culture, for in Yucatán there is to be found the entire range of sophistication from primitive tribesmen to Méridanos educated in Paris or New York.

Therefore the methods ordinarily employed by an ethnologist working among a primitive people are not alone adequate. The ethnologist may justly assume that the group he studies is a fair sample of a larger tribal culture. But in present-day Yucatán the community units are not self sufficient. The institutions that control each community are in part shaped from without, and at the same time bound up within a larger, more inclusive society. It is this larger society which must be the object of study. A description of the folkways characterizing some selected village will not adequately describe Yucatecan life; it must be studied as a thing in itself. It is not suggested, however, that the community survey of the ethnological sort be abandoned. The mere study of the formal political or social institution from the point of view of a student working in Mérida would fail to take into account the unwritten ways of the folk which still to a very great degree determine the behavior of the inhabitants of Yucatán. Community investigations must therefore be made. There will have to be more than one survey, because culture is not homogeneous in the peninsula. But they should be carried on with constant reference to the larger society with which the village life is now inseparably associated.

Briefly, it is proposed that the project include two closely interrelated divisions. The first is a study of Yucatecan society, regarded as a single entity. This would be carried on with Mérida as a base and would include within its consideration the life of that city, as well as the more explicit social, economic and political organization of the state. But one can not begin by grappling with the whole of Yucatán; the problem will have to be broken up into a series of special topics, each of which can be the object of research.

The second division of the program proposed by Dr. Redfield consists of several community studies, wherein attention will be directed to selected local communities. The studies will be year-round projects, of the sort commonly made by ethnologists, except that their purpose will be to record the culture of the community as it now is, not merely to report such unmodified native practices as remain. It is therefore proposed that in addition to the usual collection of folklore and items of local custom, the work comprise an accurate record of the round of life in its entire setting. This setting includes the larger Yucatecan society. It is therefore desirable that both divisions of the program be carried on at the same time, so that each, in referring to the other, may find, suggestion and explanation. In 1931, Dr. Redfield will spend six months in Yucatán, undertaking the first steps of the more general study and selecting the communities best suited for special investigation. At the same time he will be on the lookout for properly qualified individuals to carry on, in future

years, the unit studies. Linguistic research, an integral part of the study of the living Maya, remains to be considered. Thorough investigation of the large and territorially wide-spread group of tongues constituting the Maya stock may confidently be expected to throw much light upon the broader linguistic problems of aboriginal America. This, and its bearing upon linguistic science as a whole, need not concern us here, as at the moment we are primarily interested in its application to specific questions of Maya history. Seen from that point of view, the work is of undoubted significance. First, comparative analysis of the different Maya dialects should permit judgment as to the amount of time which has elapsed since they ceased to form part of a single parent language, and as to the order and antiquity of their separation. Second, the study of vocabularies might possibly indicate, by common possession of terms for objects not found, or activities no longer pursued in their present habitats, the nature of the country originally inhabited by the Maya. Third, knowledge of modern Maya is the first step toward ultimate reading of those parts of inscriptions which are not now decipherable. If Maya hieroglyphs had been pure picture-writing, language would, of course, not enter into attempts to read them. But there is every reason to suppose that they were partly phonetic, or at least that they expressed phonetic elements by a sort of rebus-writing. He who would decipher the glyphs must, therefore, necessarily know Maya; perhaps not the Maya of today, nor possibly even the colloquial speech of the Old Empire. The glyphs, it may be, record an archaic ceremonial language, as so many of our monuments perpetuate dead Latin. If so, the mere learning of modern Maya will not suffice, and the professional linguist will have to be called upon for reconstruction by comparative means of the Maya "Sanskrit."

What is hoped will be an intensive and long-time research upon the Maya languages was inaugurated during the past winter. Dr. Manuel J. Andrade came to Yucatán under the auspices of the Department of Anthropology of the University of Chicago, and using Chichén Itzá as headquarters devoted several months to Yucatecan Maya. Later in the season he visited the Huasteca, a tribe of northern Veracruz whose speech is Maya, but whose culture is un-Maya.

For the coming year the Department of Anthropology of the University of Chicago and Carnegie Institution are cooperating to enable Dr. Andrade to continue his investigation. He will go to British Honduras to study isolated Maya groups in that country and will later accompany Dr. Morley on an expedition to the Usumacinta River, where there are still living the Lacandonese, a small remnant of the last of the truly wild Maya.

There have now been considered the projects in physical anthropology, in medicine, in sociology and in linguistics which have been undertaken to enable us to understand the Maya of today, and so to permit us to judge more accurately than would otherwise be possible, of what the ancient Maya were and how they acted. The gap between the present and the prehistoric past must be bridged by study of the documentary history of the nearly 400 years which have elapsed since the Conquest. Its direct relations to archaeology are numerous and important. The accounts of the conquerors and early ecclesiastics contain much detailed information as to the aboriginal condition of the Maya. They also make clear the methods worked out by the incoming Spaniards for the government and control of the native population, and so explain the basis upon which modern society rests. To make an extended investigation of the history of Yucatán, Dr. France Scholes, Head of the Department of History of the University of New Mexico, will join the staff of the Institution in 1931 as a member of the Section of American History, giving, by arrangement with the University, half his time to the work.

Another documentary project shortly to be undertaken will go further into the past than does examination of the Spanish sources. It will consist of a collation of the Books of Chilam Balam. These were written by native Maya shortly after the Conquest. They are transcriptions in the Latin character, of pre-existing historic records kept in hieroglyphic writing. The Books of Chilam Balam are of the utmost value, for they give in outline the events of the pre-Columbian period. Their time counts also extend into the historic period, thus offering one category of evidence for correlating Maya and Christian chronology. The books have not fully been translated. This task will be completed and the various texts will be compared by Mr. Ralph Roys, who in 1931 will become a special investigator for the Section of American History.

It is important to know the racial makeup of the Maya, their present health, customs, and the events of their recent career. It is essential that we should learn from the ruins their distribution and their arts in the centuries before the Conquest. But the "hows" of all these things, to say nothing of the even more significant "whys," we can not grasp; in other words, we can not write history until we understand the environment which from the earliest times to the present day must have played so large a part in shaping the course of their existence.

Environmentally, the Maya country is far from uniform. The northern part of Yucatán is semi-arid subtropics, the Petén region is humid jungle, the highlands of Guatemala are temperate. There is almost every sort of country—desert, mountain, coastal swamp.

And yet before we are through we must know the topography of all these regions, their rocks, their soils, their weather and the plants and animals which inhabit them. Such data are gradually being acquired by many agencies, but to combine them into comprehensible form as a background for either the biologist or the student of man requires the synthesizing methods of ecology. The common desire for a broad yet accurate grasp of conditions in a large and significant area has led to consideration of plans for association, in Middle American research, of the Department of Biology of the University of Michigan and the Carnegie Institution. The University is tentatively contemplating a general biological survey starting in Yucatán and eventually extending to other districts. The Institution hopes to undertake studies in geology. And jointly the two would strive to interest other groups in such investigations in physical geography and meteorology as are necessary to round out the picture.

Through the good offices of President Ruthven of the University of Michigan, who from the beginning has taken the keenest and most helpful interest in the project, Dr. F. M. Gaige came to Yucatán in the winter of 1930 for several weeks of reconnaissance. He reports that not only is there a vast amount of valuable work to be done in the mere cataloging of species, both of plants and animals, but that intensive studies of local distributions and of life histories, if carried out in the light of geological and meteorological knowledge, would open avenues of approach to some of the most fundamental problems of biology. Needless to say, the Institution would welcome warmly the entry of the University into this field and would do everything in its power to be of service in forwarding its direct program and in stimulating any collateral researches which would render it more effective.

It will by now have become evident that to carry the investigation of Maya prehistory, or any similar project of serious and comprehensive nature, to a successful issue, one must build up a whole complex of associated researches. But this is not easily done. One can not employ first-rate authorities in every branch of science nor, even were that possible could one expect their best efforts if they considered their work a side-show, as it were, of archaeology. There has to be give as well as take; definite benefits, both practical and intellectual, must be offered in order to induce institutions and individuals to throw themselves wholeheartedly into the field. Such advantages are believed, in the present case, to exist.

On the practical side, the Institution is already operating both in Mexico and in Guatemala; it has established friendly relations with federal, state, and local authorities, and with the people. It has headquarters at Chichén Itzá, Uaxactún and Guatemala

City. The members of its staff are familiar with customs requirements, transportation facilities and bush conditions. Anyone who has operated off the beaten track in foreign countries can appreciate how such contacts and such sorts of information help in planning, budgeting, equipping and running an expedition.

Material considerations are, however, relatively much less important than the scientific profits which may be expected to accrue from cooperative endeavor. The botanist or the zoologist needs the data and the results of other workers fully as much as does the historian. No research can fail to go farther and to strike deeper if it be carried on in conjunction with other researches dealing with the same general body of facts. For example, the biologist studying the distribution of plants and animals in Yucatán should know the extent and approximate period of any wholesale deforestations which have occurred in the peninsula. These data the archaeologist working in connection with the agronomist will presumably be able to give him. The biologist, no less than the student of man, must understand, the climate of the region and its geological history and make-up. Research workers in medicine, to take another instance, find it necessary to call on the archaeologist for estimates of population density in former times; physical anthropologist for the racial constitution of the present population, on the biologist for the ranges, habits and life-histories of noxious organisms; upon the nutritionist for the nature of the food supply; upon meteorologist for statistics as to seasonal fluctuations of the weather, the ethnologist for information as to the social practices which form potent a factor in all problems of epidemiology. And so one might go on indefinitely, pointing out useful, even essential, interlockings between various sciences.

One other point. Field investigations as a rule lack continuity, particularly when prosecuted in foreign countries. Inaccessible regions are seen for brief periods; often they are visited but once. The result is that the student has the most fleeting glimpses of conditions which deserve long-continued observation; he acquires mere scraps of knowledge, when he should have full series of data. The all-important element of passing time can not properly be gauged, and so perspective is lost. Any opportunity, therefore, to work throughout the cycle of the seasons and to repeat and, check observations over a period of years should, if possible, be seized.

The stations of the Institution are always open; the work in Middle America is expected to continue indefinitely. The field is almost untouched; it comprises every sort of environment. Participation in the survey, either directly or indirectly, would accordingly seem to give promise of sound and significant results in any one of the biological or geographical sciences.

The survey would also appear to offer occasion for a new type of coordinated research in the humanistic disciplines. The living Maya exemplify in the clearest way a number of most important historic and social phenomena. They present, for instance, a splendid example of what occurs when a dense native population comes under the influence of a small intruding group of superior culture. The same sort of thing has happened again and again throughout the course of history and in all lands. And it has been perhaps the strongest single force in shaping the development of the Latin American nations.

Viewing the New World by and large, we find that at the Conquest one of two things usually took place. Either the Indians were exterminated or they were not. Where, as in most parts of the United States and of eastern South America, the aborigines were few and of rude culture they quickly disappeared. In Middle America and western South America, however, the native populations were dense and relatively civilized. What might have happened had the discovery been delayed but a few centuries, and the Aztec and Inca states been given time to expand, to stiffen, and to weld themselves together, forms fascinating food for speculation. The whole course of world events would doubtless have been changed. But the Spanish came, the flimsy political structures of Mexico and Peru fell apart, the nations were intellectually decapitated by the destruction of the small theocratic upper classes, in whom resided all power and all learning; and there were left the teeming millions which from the sixteenth century on have formed the body of the population. They have influenced the Caucasian immigrants quite as much as the latter have affected them. The social system and government of great areas in Latin America are the outcome of the blending of the two groups. Analysis of the interplay of racial and cultural forces, past and present, is essential to understand conditions in those countries; and knowledge of what has there occurred will supply invaluable material for the scientific study of often more complex, but fundamentally not dissimilar, conditions' produced by military adventure and colonization in other parts of the world.

This matter of racial and cultural adjustments is surely one of the most portentous which faces us today. We have abolished space and we are busily engaged in veneering western material civilization and ideas over the entire face of the globe. The resultant clash is responsible, at bottom, for much of what is now happening in China, in India, in Egypt, in South Africa, even in Russia. It appears, indeed, not unlikely that the historian of the future will see in these phenomena as great significance for the formation of his world as he can observe in the politics, say, of nine-

teenth century Europe. Yet to the details of that period a hundred scholars now devote their lives for every one who considers such fundamental ethnic relationships as are illustrated by the contact of the Indian and the Caucasian.

Research upon this particular phase of inter-racial contact lies, it is true, in the domain of the Americanist, and its immediate problems are essentially American. But it has worldwide implications, and it is of vital importance to the entire range of the sciences of man. The study is of appalling intricacy because it deals with human beings, and it is therefore beset with the multitudinous psychological bafflements, biological obscurities and gaps in the historic record which render the consideration of mankind so much more complex than any other research can possibly be.

Such inherent difficulties are, of course, largely responsible for the slow development of humanistic as compared to biological knowledge, and for its snail-like progress when contrasted with the rapid advance of the physical sciences. But students of man have also been culpable in failing to face the issue. Daunted by the awesome bulk of human history, or, human evolution, or the nature of man, or whatever one chooses to call it, and shrinking before the grievous magnitude and the seemingly endless ramifications of their task, they have buried their heads, ostrich-like, in the comfortable sand-heaps of specialization.

Specialization, of course, is necessary, for it is the splitting up of something too large for immediate comprehension in its entirety to permit intensive consideration of its parts. The process, however, implies eventual reassembly of those parts and ultimate visualization of the whole. But each of the many sections, the so-called disciplines, into which the study of man has perforce been subdivided pursues its own ends with almost deliberate disregard of the objectives of every other. And within the disciplines, each worker or group of workers does practically the same. We have, of course, realized the dangers of intellectual isolation, have attempted to counteract them by broadening the scope of graduate instruction, by holding mixed conventions, by establishing academies and research councils. Although such moves are certainly in the right direction, they are at best mechanistic set-ups rather than natural cooperations, and in our individual researches, our field, or laboratory, or archive investigations in those activities which are nearest our hearts and to which our best efforts inevitably are given, we have made few and but half-hearted attempts toward real association or mutual understanding.

Forced cooperation is certainly not desirable. At best it is pretty sure to be artificial and therefore unproductive. But some form of becomes essential as the humanistic sciences broaden their outlook and deepen

their researches, and there begin to be encountered phenomena too great for comprehension by any single group, yet involving principles of fundamental importance to all groups: race, for example; or environment versus heredity, or the inherent ability of mankind to increase its capacity for understanding. These things must be attacked and their underlying problems must be formulated if the study of man is to go forward.

But how? Every scholar is fully occupied with his own researches, every 'ology has its own preoccupations. In the few cases, however, where forces have been joined and the efforts of workers in several disciplines have, in one way or another been brought to bear upon a single body of significant data, or upon any one important general problem, it has always resulted that not only was the gathering and digestion of specialized information in no way retarded, but that there has come about an interchange of ideas, an intellectual cross-fertilization, immensely valuable for all participants. Such investigations have, however, been the exception rather than the rule, and for some reason, possibly from mere inertia, perhaps because certain enterprises have been over-organized or their programs too rigidly defined, they have not yet become by any means standard practice in the social sciences. Further experiment is necessary.

The survey of Yucatán is being planned with the above considerations in mind. It is based on the theory that we should concentrate, whenever we can, upon fields where specialized researches can be pursued in entire independence of each other, but where results will be cumulative and findings comparable; and where common interest, if nothing else, will foster intellectual and practical cooperation.

The general problem toward the solution of which the investigation is directed may be formulated as follows: What are the results of the meeting of two races of diverse physical make-up and differing culture? This, as has been intimated, is a matter of very great moment. No research in history, anthropology, sociology, government, religion, genetics, esthetics, can be pushed very extensively or very profoundly without encountering one aspect or another of race or culture crossing. It is a problem transcending adequate comprehension by any one group, therefore it is an ideal one for joint attack. Even so approached, however, it is still too great. One can not hope effectively to begin a study of ethnic contacts with the whole world as a field and throughout the millennia of history. We must pick a simple exemplification of the problem both in space and in time. The New World offers a splendid laboratory for the study of culture growth, and the post-Columbian period in Latin America illustrates particularly well all the phenomena incident to the meeting of diverse peoples. But Latin America, again,

is too big. We should still further reduce our preliminary objective; and so we come to Yucatán.

The area of Yucatán is small; its environment is uniform. Natural barriers isolate it from continental Mexico. For upwards of a thousand years the peninsula was the seat of a high aboriginal culture. The Spanish conquest resulted in obliteration of the externals of native civilization, in the catholicizing of the Maya, and the reduction of the dense native population to serfdom. There took place the inevitable hybridizations, racial, religious, social and economic; there were the same strifes, uprisings, readjustments, with far-reaching effects upon both elements, which have occurred wherever the Spanish found themselves overlords of crowded Indian nations. Yucatán presents an epitome of historical events and present-day conditions in much of Latin America; and, to a less precise but still significant degree, it exemplifies what has happened at all periods and in all parts of the world when, after military conquest, the will of a potent minority is enforced upon a race of lower culture.

It has seemed wise to formulate, at this early stage of the survey, only a few general principles. Each unit of research should be intensive, employing the technical methods and striving for the special aims of its proper discipline; but there should constantly be kept in mind its ultimate bearing upon the basic question of race-contacts; and there should also be fostered an historical point of view, in other words, a consciousness of the time relation of all phenomena. And, finally, by field conferences, such as the one held during the past winter at Chichén Itzá, and by meetings elsewhere, close personal and intellectual touch must be kept between all concerned.

There have already been discussed the archaeological, historical, sociological, and environmental units of the survey. And mention has been made of other desirable researches. The difficulty lies not in what to do, but in selecting what is most important to do, in deciding how best to do it, and in finding the men and the means with which to get it done. No one institution can possibly handle a project so large and so varied. Success is to be attained it must come through realization by many agencies that the field is a significant one, through confidence that it is being developed in the proper way and through belief that investment of effort in cooperative research will bring valuable scientific dividends.

ALFRED V. KIDDER

Division of Historical Research

YB 30:101–104, 1931

The Division of Historical Research is dedicated to studies upon the social and intellectual, in so far as these may be distinguished from the biological, evolution of the human race. Its three sections devote their to various aspects of what is really a single endeavor, namely, the attempt to understand the whys and the wherefores of man's long struggle toward more perfect living. The Section of Aboriginal American History, considers the rise of civilization as exemplified by the career of the native races of the New World. The Section of United States History concerns itself with the development of a typical modern state as well as with the interactions between Western European and indigenous American cultures.

SECTION OF ABORIGINAL AMERICAN HISTORY

The two Americas form an ideal laboratory for studies upon the genetics of civilization. The Indians came into the New World as savages, bringing with them no more than the rudiments of culture; and they never, as we can now see, received any significant stimulus from outside until the arrival of the Europeans in the early sixteenth century. Hence their entire development was an autochthonous one, isolated, independent. Yet in major outline it was extraordinarily like that of the of Europe and Africa and Asia. But it seems to have been a some what more simple and more straightforward progress, evidently much less interrupted by the sweeps and counter sweeps of population which at times retarded and at times accelerated the march of civilization in the Eastern hemisphere here, and which render its story so exceedingly difficult to unravel. Furthermore, the archaeological remains of the Americas are younger, on the average by several thousand years, than those of the Old World; they are therefore in a generally better state of preservation, and they have been far less overlaid or destroyed by the activities of recent peoples. If, therefore, the archaeological investigation of the New World be intelligently conceived and vigorously prosecuted, the history of the Indian's rise from savagery can doubtless be reconstructed with a relatively high degree of accuracy. The resulting data will prove of much value for comparative purposes; the methods developed and the insight gained into the mechanics of culture growth will be

useful for attack upon the more complex problems of the Old World.

The field presented by the American continents is of course enormous. Some parts of it, however, are greater, or at least of more immediate, importance than others. These should naturally be attacked first. The Carnegie Institution, in joining itself to the many agencies engaged in researches upon New World prehistory, has concentrated its effort upon two areas: Middle America, where the Maya achieved one of the most brilliant and most widely influential of Indian civilizations; and Southwestern United States, where the career of the Pueblos exemplifies very clearly first steps in the organization of a communal society based on agriculture.

Dr. Morley and his associates have been at work on the Maya for nearly 20 years. After a preliminary period of exploration, resulting in formulation of certain definite historical problems, the Institution turned to the excavation of two sites which gave promise of yielding significant data for their solution: Uaxactún, the oldest known Maya city, and Chichén Itzá, an outstanding center of the New Empire.

The investigations at Uaxactún and Chichén Itzá have been recorded, from year to year, in the annual reports of the Institution. During period covered by the present *Year Book* the two projects have continued. At Chichén Itzá, Dr. Morley and his staff devoted their time to the study of buildings excavated in former seasons, to the writing of monographs upon them, and to the perfecting of plans for comparative analytical research upon Maya architecture. Dr. Morley also headed an expedition to the ruins of Yaxchilán, in the Usumacinta drainage, where a number of new calendrical inscriptions were discovered.

At Uaxactún, Mr. Smith carried forward the excavations with great success. He completed the examination of the very old deposits underlying one of the plazas of the city, accumulating pottery and other materials which will throw light upon the vexed question of Maya cultural origins. He also cleared an early temple enclosed within and preserved by later construction, wherein he found graves containing mortuary pottery of extraordinarily high artistic excellence.

Mr. Ricketson spent the winter in Guatemala City. With Mrs. Ricketson he studied the ceramic collections from Uaxactún, and worked on the report covering the earlier excavations there. He also made reconnaissance trips in the Guatemala highlands with a view to laying plans for future investigation of that very little known but archaeologically significant region. President Merriam, Mr. Roberts and the Chairman visited Guatemala in January to confer with members of the Government, to consult with Mr. Ricketson and to examine various archaeological sites. Mr. Roberts took

leave of absence in the latter part of the winter to excavate in Panama for the Peabody Museum of Harvard. His studies of Maya pottery continue.

The archaeological researches of the Institution in the Maya field have been prosecuted energetically. They have proved very fruitful. But from the time of their inauguration by Dr. Morley in 1914, it has been realized that the unsupported findings of archaeology could not be expected to result in more than an incomplete and one-sided picture of the career of the Maya; that they could not fully be interpreted save with knowledge of the manifold factors of environment and race which influenced and molded that career; and that no real history of the Maya could be written until full cooperation had been established with workers in other branches of science. These considerations were discussed in the *Year Book* for 1929-30. As was there stated, the necessity for assistance from non-archaeological disciplines has led to the organization of a general scientific survey of the region formerly inhabited by the Maya.

In Yucatán various survey projects have gone forward. Dr. Redfield, of the University of Chicago, has continued his sociological study of the living Maya. Dr. Steggerda, of the Institution's Department of Genetics, pursued the investigations in physical anthropology begun by Dr. Williams, checked former determinations of basal metabolism and inaugurated a research upon the growth of Indian children which it is hoped may be followed over a long term of years. Dr. Andrade, now jointly employed by University of Chicago and Carnegie Institution, carried forward his work on Maya linguistics. The medical survey of Yucatán, under Dr. Shattuck of Harvard, was not in the field, Dr. Shattuck having been engaged during the winter in preparing the report upon the first two years' investigation. In the summer of 1931, however, a party under Shattuck's direction will undertake a check of the present prevalence of malaria and the dysenteries among the population of the peninsula. Mr. Scholes has begun work on the documentary history of Yucatán. Mr. Roys is engaged in translating and collating the Books of Chilam, which are very important early Maya documents written, in the Latin script.

All the above investigations concern themselves with the Maya people, their race, physical make-up, health, customs, language, recent history. No valid appraisal of the career of their ancestor's can be made without knowledge to be derived from such researches. No less imperative clear understanding of the land in which the Maya lived and still live. Environmental studies are therefore also being made. The much valued cooperation of the University of Michigan continues. During the winter Dr. Van Tyne, ornithologist; Dr. Murie, mammologist; and Dr. Bartlett, botanist, were sent by the University of Michigan to Uaxactún, where

they made the first series of biological observations and did the first thorough collecting in Petén, the center of the Maya Old Empire. The United States Geological Survey also cooperated most effectively by permitting Dr. Cooke to accompany the Uaxactún party for the purpose of gathering geological data. As result of his examination of the Petén, Dr. Cooke believes it possible that the bajos, or seasonal swamps, may have been lakes as recently as the time of occupancy of the Petén by the Maya. If this hypothesis be verified it will serve to explain many hitherto very puzzling aspects of Maya history.

The cooperation of scholars representing various disciplines is indispensable for the progress of archaeology; it is also of first-rate value to the other sciences themselves. The biologist of course needs the assistance the geologist; the medical man must have data which only the biologist can supply, and so on. Close touch should accordingly be kept between all participants, not only for the pooling of information, but for the formulation of broad problems underlying several or all of the unit researches, and for devising means for their solution. For this purpose annual conferences are held at Chichén Itzá. The meeting of the present year was attended by Mr. Morley, Mr. Ruppert, Mr. Pollock, Mr. Scholes, Mr. Bolles, Dr. Cole and Dr. Redfield of the University of Chicago, Dr. Andrade, Dr. Steggerda, Señor Juan Martínez Hernández and the Chairman.

At the close of the period under review there came from the press monograph of Mr. and Mrs. Morris and Mr. Charlott on the Temple the Warriors. This is the first definitive publication upon a unit of the Chichén Itzá project. In content and in illustration it sets a new standard in the presentation of results of excavation in the Maya field.

Other major publications of the Division now in preparation are: Morley's compendious work on the inscriptions of Petén, Mr. Ruppert's volume on the Caracol at Chichén Itzá; Messrs. Thompson and Pollock's paper describing the ruins of Cobá; Dr. Andrade's Maya grammar. Dr. Shattuck's medical report has already been mentioned.

The Division suffered a severe loss in the death, on March 22, 1931, of Dr. John E. Teeple, Research Associate, at the age of 57. Dr. Teeple a chemist by profession, having taken up the study of the Maya hieroglyphic inscriptions in 1924 as an avocation. His earliest contribution in this field were of such outstanding importance that he was appointed a Research Associate of the Institution in 1929, continuing as such until death. The results of his brief six years of investigation are embodied in his *Maya Astronomy*, published by the Institution last year (Teeple 1931). Dr. Teeple's untimely death has removed from Maya research one of its most productive contributors.

ALFRED V. KIDDER

Division of Historical Research

YB 31: 89–91, 116, 117, 1932

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating to the rise of native civilization in the New World, its two principal fields being the Maya area in Mexico and Central America and the Pueblo area of southwestern United States. The Section of United States History is devoted to research upon the growth of Western European institutions in the Americas. The Section of the History of Science strives to bring together and to make available for interpretation the at present widely scattered and uncoordinated data which bear upon the acquirement and transmission of ordered knowledge.

The two outstanding problems of pre-Columbian New World history are those of the peopling of the American continents and of the rise, in this hemisphere, of native civilization. The true position of the American Indian among the races of man can not be evaluated until we know who he was, and whence, why, when and how he came; nor can the significance of his career be understood unless we have information as to what elements of culture he brought with him, how much he developed independently, and how he managed to build up the complex social, religious and economic structures which he had possessed for centuries before the coming of Europeans. These two questions of origin and growth are naturally fundamental for Americanists; they are also of extreme importance for the study of anthropology in the broader sense, for the one strikes back to the primary diffusions of the human stock, while the second links into the vast riddle of man's perennial upward striving.

From the limitless range of possible activities in New World research this Section has elected to devote itself to the rise of native American civilization; and, within that field, on the principle of nuclear attack, to operate in two regions whose people were pre-eminent as builders of aboriginal culture, the Maya area of Middle America and the Pueblo country in the southwestern United States.

The Section's early work upon the Maya was purely archaeological. Its major efforts, indeed, still devoted to recovery, by exploration and excavation of factual data bearing upon the prehistoric period. But as such materials began to accumulate, and an attempt was made to interpret them in terms of history, it became clear that temples and pottery and ornaments,

even hieroglyphic dates, were, in themselves, relatively meaningless. It was perceived, as must inevitably occur in any archaeological research, that very little progress could be made toward an understanding of how these things came to be what they were and where they were, to say nothing of what they meant, without accurate knowledge of a host of environmental factors which the archaeologist has neither the ability nor the time to study: the geology of the region, for example, its flora and fauna, its climate. Furthermore, there are certain flank-attacks, so to speak, which may be made upon archaeological problems, advances along collateral lines which result in accumulation of data to supplement or to facilitate comprehension of the meager and fragmentary products of excavation. Documentary history offers one such approach by giving us, along with many other things, a picture of native life at the time of the conquest, which is indispensable for interpretation of ancient remains. Ethnologists, working on the present-day Maya, learn further facts useful for the same end. Linguistic study is an invaluable aid in that it permits deduction as to the specific and general relationships of groups, as well as concerning their contacts with people of other stocks. Racial questions must be considered in the light of data only to be gathered by the physical anthropologist. Medical research throws light upon the history of diseases. Agronomy tells us of the capabilities of the soil and the probable methods of its cultivation.

All this is obvious enough; or should be. But archaeologists, like many other specialized workers in the human field, have been so busy with their own absorbing tillage that they have generally failed to realize the urgent necessity of developing some method by which the results of other disciplines may be made available for their use.

In an attempt to work out such a method, the Division has sponsored a general scientific survey of the Maya area. Its scope and the financial and organizational difficulties encountered have been discussed in a previous report [Chapter 1.18]. The undertaking is still in the stage of experimentation. It has not been long enough under weigh to have permitted adequate testing of its more practical arrangements. One can not yet be sure of mustering the funds and the personnel which will be necessary to bring so many-sided a research to its logically full development. Mutually satisfactory relations must be established with a large number of cooperating agencies. The efforts of a very heterogeneous group of students must be coordinated and their diverse interests satisfactorily harmonized. But in spite of all uncertainties, in spite, too, of the briefness and inadequacy of the tryout, one may feel confidence in the soundness of this type of approach. For the activities of the collaborators, the historian, the

linguist, the ethnologist, the physical anthropologist, have not only helped the archaeologist, but have resulted in the formulation of a host of special problems of modern life which are themselves insoluble save on the evidence of what has gone before. Thus the present and the past have been firmly interlinked and the realization has been driven home that neither one can be understood save in the light of the other. So there has been a shift in emphasis, or rather a broadening of outlook; and what was originally the study of a single episode, the pre-Columbian era of Maya greatness, has become the envisagement of a continuously sweeping current of history. The biological, geological and climatological studies are likewise serving to spread an environmental screen upon which the moving picture of a people's fortunes may be thrown in clear focus.

Few more favorable fields than the Maya country could be found upon which to come to grips with the fundamentals of history and of anthropology, nor for bringing about the much-needed recognition of the essential unity of their aims. Study of the Maya from the earliest times to the present involves consideration of age-long and world-wide problems: the relation of man to his habitat, the spread and interaction of nascent cultures, the origin of higher civilization, the decay and fall of social orders, the clash of native and European races, the adjustments between conquerors and conquered, the impact of twentieth century ideas upon backward populations.

It is difficult to escape the conviction that only by coordinated research, involving the cooperation of all the disciplines devoted to the study of man, and the collateral support of many biological and physical sciences, can we attain understanding of any given episode in human history. But any such research is obviously costly, complex and long. And when the anthropologist surveys the entire potential range of his labors, and realizes how rapidly are passing unrecorded away the languages and customs which are the very fundamentals of his science, he must inevitably feel that the mere factor of time can not permit him to spend his precious years or his limited funds in detailed work with less hurried colleagues in what is, from the total point of view, a very small corner of the field. He must harvest his whole crop before the devastating flood of Western European culture shall have washed it completely away. But in spite of all this, indeed because of it, there is a very real reason for carrying, forward, concurrently with the essential salvage, a certain number of intensive projects in intimate association with other scholars. Anthropology, as a science, has not yet progressed sufficiently far to know just what facts are most essential for it to gather. Ideally, of course, everything should be observed and every thing recorded. Practically, this is impossible.

The ethnological field worker must pick and choose. He can not, however, at this stage of the game, collect selectively without danger, nay without certainty, of missing vital data, because their bearing is not obviously apparent. Hence, both for the well-rounded growth of anthropology and for the immediate purposes of the great amount of raw collecting which it is our absolute duty to carry forward during the next few decades, it is necessary to test our methods and interpret our findings as we go along by the selection of certain significant groups which shall be studied both in historical perspective and from the viewpoint of environmental relationships, as well as with regard to their functional response to the exigencies of the modern world. No plea of urgency should influence us to forsake this indispensable type of research. As a matter of fact, the extensive and the intensive should proceed concurrently. Neither, in the long run, can be of full value if the other has been slighted. It is a firm belief in the truth of this proposition that has induced the Section of Aboriginal American History to undertake its present work in the Maya field.

SUMMARY OF THE MAYA SURVEY

Archaeologically, this has been perhaps the most productive year of the Institution's nearly two decades in the Middle American field. At Chichén Itzá, the work at the Mercado has transformed a meaningless heap of tumbled stone into a beautiful and understandable example of Nahua-Maya architecture at its apogee; the investigation of the Monjas inaugurates a study which will surely throw much light on the earlier, purely Maya, period. The Calakmul expedition brought knowledge of a very large, strategically located and hieroglyphically very fully documented Old Empire city in a region whose further exploration promises much of vital interest. Uaxactún yielded a number of richly stocked tombs; the excavation of the "palace" throws light on an important type of building which, in the Petén, has not hitherto been examined; but probably most valuable of all was the discovery of the prolific and well-stratified rubbish deposit, the abundant sherd material from which will add greatly to our knowledge of Old Empire ceramics. The architectural-ceramic survey demonstrated, in northern Yucatán, the soundness of its methods and resulted in collection of data to found a truly scientific study of the archaeology of that area. In Guatemala, Dr. Lothrop's work constituted a start at unraveling the complex problems of the highlands.

The year's accumulation of data has been unusually great. The difficulty of making these data promptly and fully available remains acute. The published report, presenting both the facts and the investigator's

deductions there from, is the end-product of all research. In archaeology, however, materials pile up so rapidly, and their study is so long and so arduous a process, that writing proceeds very slowly. The result is that no member of the Section's archaeological staff, save Mr. Ricketson, is fully abreast, in the matter of publication of his fieldwork; some, indeed, are several years behind. It would seem obvious that field activity should, in each case, stop until the individual concerned has caught up. But many practical considerations, contracts with governments, the holding together of digging and transportation organizations, urge continuance. Very anxious thought is being given to this problem.

A number of non-archaeological researches have gone forward, with Guatemala the principal center of activity. There, geographical reconnaissances have been begun, medical studies inaugurated, as well as volcanological observations by Dr. Zies of the Institution's Geophysical Laboratory. A party from Duke University and the University of Michigan is, during the present summer, at work upon the biology of the inland waters of Yucatán; their results will be reported in the next *Year Book*. The ethnology of Yucatán continues under study by Dr. Redfield's group; Dr. Steggerda made his annual visit to Chichén Itzá for anthropometric purposes. Mr. Scholes is in Spain collecting archive materials bearing on the history of the Maya; Mr. Roys is translating and annotating the historical sources in the Maya idiom. All these projects are making satisfactory progress. There remain, however, a number of really essential additions to the list.

The need for a topographic survey of the Guatemala highlands has already been stressed. The geographic work in that region should also be supplemented by specific attention to geological and volcanological problems. The geology of the Petén and of northern Yucatán must eventually be carefully investigated. Nothing at all has as yet been done upon the basic environmental factor of climate. Agronomy clamors for attention. The biological field has hardly been scratched.

1.21.

ALFRED V. KIDDER

Division of Historical Research

YB 32:81-83, 1933

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating to the rise of native civilization in the New World, its two principal fields being the Maya area in Mexico and Central America and the Pueblo area of southwestern United States. The Section of United States History conducts research upon the growth of Western European institutions in the Americas. The Section of the History of Science strives to bring together and to make available for interpretation the at present widely scattered and uncoordinated data which bear, upon the acquirement and transmission of ordered knowledge.

SECTION OF ABORIGINAL AMERICAN HISTORY

As has been stated in previous reports, the present major effort of the Section is the attempt to develop a many-sided attack upon the historical problems of those parts of Mexico and Central America which, in pre-Columbian times, were the seat of the Maya civilization.

Carnegie Institution's first work in the Maya field was purely archaeological. Through exploration, and subsequently by excavation, studies were made of the distribution of Maya remains, and information was gathered regarding the nature of Maya culture at various periods. Progress of the research brought increasing realization of the importance of the role played by the Maya in building up aboriginal civilization in Middle America; and it also became obvious that the career of the Maya, were it sufficiently well understood, could be counted upon to provide valuable materials for the comparative study of civilization as a social-evolutionary process. But at the same time it was evident that to be of maximum usefulness for Middle American culture history and particularly for broader comparative purposes, our knowledge of the Maya must be much more comprehensive than we could hope to make it by archaeological means alone. For, as was stressed in the above-mentioned reports, the spade of the excavator can recover only factual data, and the interpretation of those data, in terms of the factors motivating and directing human action, can only be accomplished in the light of information as to the physical environment in which the Maya lived, as to their racial and menial make-up, as to their recent history

and present, social practices. With none of these problems is the archaeologist fitted to deal. So assistance was solicited, from workers in many non-archaeological fields, and there has developed a program of investigation amounting to a general scientific survey of the Maya area.

Archaeological work and research in documentary history are going forward under the auspices of this Division; studies on physical anthropology are being prosecuted by the Institution's Department of Genetics; the food supply of the modern Maya and its effect upon basal metabolism are studied by the Nutrition Laboratory; cooperation with University of Chicago permits work on linguistics and social anthropology; with the School of Public Health of Harvard University upon tropical medicine; with Clark University and University of Florida upon geography; with University of Michigan upon botany and zoology; with Duke University upon the biology of the inland waters of Yucatán.

During the year under review, notable progress has been made along many lines. At Chichén Itzá the program of excavation and repair of outstandingly important structures has been advanced by completion of work upon the Monjas, the most complex and architecturally the most instructive building in the city. An expedition into Campeche resulted in discovery of several new sites, as well as in closing the gap which has hitherto existed between the territory explored from the north and that reached from the south. At Uaxactún the investigation of the so-called "Palace" was continued; and various smaller structures yielded materials for the ceramic studies which are proving so valuable for reconstruction of the cultural history of the Old Empire Maya. The ethnological survey of Yucatán has been forwarded by observations upon modern life in Mérida, the capital; in Dzitas, a large provincial town; and in the primitive communities in the forests of the former Territory of Quintana Roo. Anthropometric record of the development of Maya children has continued in certain villages near Chichén Itzá. There was begun a botanical survey of the grasslands of the Department of the Petén in northern Guatemala, a by-product of which was the finding of two large ruined cities, hitherto unknown; and, during the summer of 1932, a party investigated biological conditions in the cenotes, or natural wells, of Yucatán. Archive work in Spain and study of native Maya literature continued. The history of certain outstanding Maya families has been traced.

The above, and certain smaller but no less important, researches are reported upon in the body of this report. The mere listing of so considerable a group of activities implies the gathering of great amounts of information as to the past and present life of the Maya;

and as to the environments, both physical and social, in which they have pursued their career. All this work, much of it carried on under great hardship and no little menace to health; all the toilsome accumulation of facts; all the expenditure of energy and funds, has been undertaken in order to find out how and why the Maya raised themselves from savagery to civilization, how and why that civilization fell, and what has brought about the conditions under which the Maya exist today. Could such knowledge even partially be attained, a highly significant contribution would be made to our understanding of that baffling creature, man. For the more we learn of his past, the more closely we analyze his history throughout time and across the continents, the more clearly can it be seen that in spite of the multiplicity of blindly fortuitous circumstances which have shunted him in this or that direction, which have brought some groups to dominance and others to obliteration; that in spite of all this, man's destiny has been shaped by the possession of certain attributes, or potentialities, or urges, or whatever one chooses to call them, which have resulted in fundamental similarity of development among all peoples. So the story of such a group as the Maya, who have run the full gamut of success and vicissitude, cannot fail to be of deep significance for the synthesis of human history which must some day be attempted. However, and this is the crux of the whole matter, no amount of fact-gathering will by itself tell that, or any other, story. The raw data must not only be collected, they must also be correlated in such a way as to bring insight into the workings of those infinitely complex concatenations of exterior circumstance and inherent human qualities which have always directed and will ever continue to direct the course of history.

The task of correlation and interpretation is manifestly of a far higher magnitude of difficulty than the accumulation of materials. It may, indeed, well be doubted whether it is possible to perceive the nature and to evaluate the action of the forces which have governed the career of any ancient people. But if the attempt be not at least envisaged, archaeology becomes mere antiquarianism! This is so self-evident that its statement here would be unnecessary, were it not for the fact that our survey is a deliberately planned experiment, undertaken with the express purpose of determining whether such correlations and such interpretations are possible; whether, in short, archaeological studies can sufficiently be illuminated and vivified to render them productive of valid historical conclusions.

Results can not, in any case, be quickly achieved. Merely to assemble the requisite mass of raw data will require long effort. Much time and large funds will be needed for the many necessary investigations. But it is

not possible to begin too soon to look forward to the ultimate goal. Every worker can produce materials which will be more serviceable for his own purposes, and of much greater usefulness for the eventual synthesis, if he sees his activities in their relation to the whole project and keeps in mind the broader ends for which they are undertaken. To do this the members of the survey must know what is going on; the success of the program depends, indeed, upon close touch being kept between all participants. Current research can of course be followed in the *Year Book* and by reading the conclusions, at least, of all publications of the survey. Personal contacts are of even greater importance. By word of mouth one can learn most effectively what one's colleagues are thinking and deducing, what they really see in their work, what they are planning for the future. Through such intercourse comes the sympathetic understanding of others' problems, the appreciation of their difficulties, and the willingness to give as well as to get, which, alone can develop the team-play so essential for the success of our most difficult undertaking.

1.22.

ALFRED V. KIDDER

Division of Historical Research

YB 33:81-82, 1934

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating to the of native civilization in the New World, its two principal fields being Maya area in Mexico and Central America and the Pueblo area of southern United States. The Section of United States History conducts research upon the growth of Western European institutions in the Americas. The Section of the History of Science strives to bring together and to make available for interpretation the at present widely scattered and uncoordinated data which bear upon the acquirement and transmission of ordered knowledge.

SECTION OF ABORIGINAL AMERICAN HISTORY

The Section is engaged in studying the career of the Maya Indians, from the earliest times to the present. Its primary objective is of course to learn the facts of Maya

history. As an aid, in this endeavor, it is also working on the language, ethnology and physical anthropology of the modern Maya. At the same time, attempt is being made to gather data regarding the environment in which these people have lived and are living, for without knowledge of this sort it is obviously impossible fully to understand why the pre-Columbian Maya achieved intellectual and artistic pre-eminence among the Central American aborigines; why their civilization fell; and how they have reacted to conditions forced upon them by the coming of European conquerors. The program of the Section therefore falls naturally into two parts, the one concerning itself with events and social conditions, the other with the ecology of the area in which those events took place and those conditions arose. The ultimate aim of the research is to paint, in the light of these two categories of information, a true historical picture.

The framework, so to speak, of the program is provided by the archaeological investigation, which covers the pre-Columbian period; and by documentary research, dealing with the four centuries that have elapsed since the discovery of Yucatán. Both endeavors have perfectly definite objectives, the reconstruction of sequent phases of Maya history. The simplicity of their aims and the fact that, as both are carried on by staff members of the Institution, their progress can be uninterrupted renders the planning and execution of the archaeological and documentary undertaking a relatively easy matter. The environmental studies, as well as those in linguistics, ethnology and physical anthropology, serve to illumine and render interpretable the findings of excavator and archivist. The direction which they must take is therefore to some extent dependent upon current needs of the central historical investigation. Furthermore, this group of projects is being carried out, for the most part, by associated or cooperating scholars, rather than by staff-members. Hence the men concerned with them can not usually devote full time to the work. Their field trips, too, must be made to fit in with other duties. This necessitates a certain degree of opportunism in developing the non-historical elements of the program. But it permits utilization, even if only intermittently, of the services of a great number of expert specialists than could well be mobilized by the Institution or any other single agency; and, most important of all, it insures a constant influx of fresh mental blood, new ideas, new methods of approach, new techniques. In spite, then, of its many administrative difficulties, and of the evident danger of diffusion of effort, it seems that a coordinated investigation of the sort which the Section is attempting to make is the most effective method for attacking with limited funds and personnel the problems of Maya history.

The most important event of the period under review was the granting by the Mexican government of a new contract to Carnegie Institution of Washington for scientific research in the Republic. Running for five years with option of renewal for an additional five years, this contract permits continuation of archaeological work at Chichén Itzá and also provides for pursuing, in other parts of the Republic, the investigation of problems in Maya history raised by the excavations in Yucatán. Throughout the 10 years during which the former agreement was in effect, the Institution has been accorded uniformly cordial and effective cooperation from all governmental authorities, both in Mexico City and in Yucatán. Thanks are especially due to Lic. Don Narciso Bassiols, Secretary of Public Education, and to Ing. Don José Reygadas y Vertiz, Director of the Department of Prehistoric Monuments, with whom Dr. Morley was in conference in December 1933. Both these gentlemen gave freely and courteously of their time to consideration of all questions involved in the renewal.

The arrangements now in force insure further prosecution, under the most favorable circumstances, of the Institution's program. Of even greater significance is the fact that the Institution is permitted to continue working side by side with Mexican scholars upon scientific problems of mutual interest, and thus to have a part, however small, in developing the close intellectual relations which are so essential for international amity. Similar opportunities are offered by the Institutions researches in the Republic of Guatemala.

1.23.

ALFRED V. KIDDER

Division of Historical Research

YB 33:91-93, 1934

PROBLEMS FORMULATED

At the beginning of this section, it was stated that various problems had as result of the 10 years of excavation at Chichén Itzá, whose solution, or perhaps better whose fuller formulation, requires investigation at other sites or in other regions. Although materials have of course been found at Chichén Itzá which bear on every possible phase of Maya history, certain of research seem of outstanding importance.

"NAHUA" ARCHITECTURE

Most structures at Chichén Itzá contain many features foreign to Classic Maya architecture and, indeed, to what seems to have been contemporary building practice in the northern part of Yucatán. Investigation has proved that all such structures are late. Their peculiarities have generally been ascribed to Nahua influence, because Nahuatl groups from continental Mexico are known to have entered Yucatán during the troublous centuries preceding the Spanish Conquest. Furthermore, certain elements of the so-called "Nahua" style (e.g. the serpent column, the vertically walled ball-court with rings, etc.) occur in the Mexican homeland of the Nahua peoples. But while presumption is very strong that the invaders were responsible for the development of the late architecture of Chichén, the extent of their contribution can not yet be gauged. It is possible, for example, that the peculiarities in question were of independent local origin and were subsequently copied in Mexico. A perhaps more plausible supposition is that the Nahua introduced a novel religious cult and a few more or less rudimentary architectural innovations; that headquarters of this cult were established at Chichén; and that Maya architects there brought the new architectural style to such full flower that it struck back, so to speak, into the region from which part of its stimulus originally came.

The above is no more than a theory. But it is susceptible of proof or disproof. Thanks to the work at Chichén, we are now thoroughly conversant with the details of the late buildings. We are therefore well equipped to begin search in the direction of Mexico for the prototypes, if such exist, of the elements which differentiate them from other Maya structures. This investigation promises much of interest, for the coast-plain of southern Veracruz, which is the logical point for first attack, is archaeologically next to unknown. It should yield valuable data not only on the question just discussed, but also upon the history of architecture in highland Mexico.

YUCATECAN ARCHITECTURE

A relatively few buildings at Chichén Itzá (e.g. Monjas, Akabzib, etc.) conform to the standards of what is called, "Renaissance" Maya architecture. Indubitable evidence shows them to antedate the "Nahua" structures. Their closest homologues seem to occur at the cities of the Puuc district to the south and west. It is therefore desirable carefully to compare the ground-plans, the masonry, and the ornamentation of the older Chichén Itzá temples and those of the Puuc, as the first step in the general survey which must be made of New Empire Maya architecture. At present our knowledge

of this subject is woefully meager. Chichén, Uxmal, Cobá, a few sites on the East Coast, and Labná in the Puuc, are the only cities which have undergone effective investigation. The study of the Puuc area should be completed, as it contains many ruins representing what is probably to be regarded as the norm of the Yucatecan renaissance. The known ruins of northern Yucatán ought also to be worked and exploration made of considerable archaeologically virgin territory which still exists in that part of the peninsula. Edzná, Holactún, Jaina and other sites in the west should next be examined because, upon stylistic grounds and in the possession of early dates, they appear to offer specially favorable opportunities for gathering information as to the arrival of southern Maya culture in Yucatán. With the above projects completed, one would be in position to attack the extremely important Chenes and Río Bec areas which, geographically at least, connect the New Empire field with the Old Empire regions of the Petén, the Usumacinta and Chiapas.

During the past year Mr. Pollock, who with Mr. Roberts is engaged in a joint architectural-ceramic study of the Maya, has been digesting the literature in preparation for carrying out the above-described program. Both it and the search for the origins of the Nahua style would strike backward from the known to the unknown, the former toward the beginnings of purely Maya architecture; the latter toward the sources of the mixed architecture of the late Chichén Itzá temples.

CERAMIC PROBLEMS

Knowledge of the Maya has been on the one hand greatly advanced and on the other hand seriously retarded by the fact that many ruins can be dated by means of the hieroglyphic inscriptions. These records provide so quick and easy a method for recovering the main outlines of Maya history that they have received the lion's share of attention, to the very unfortunate neglect of such less spectacular but more abundant, and in some ways more reliable, criteria as architecture and ceramics. An example of the results of this tendency is provided by our present inability to bring archaeological evidence effectively to bear upon the problem of the correlation of Maya and Christian chronology, because we do not know sufficiently well the "dirt" archaeology of the Maya. It has therefore been a constant aim of the Section to foster this side of Maya research, particularly in the field of ceramics. The promising results obtained at Uaxactún have already been mentioned. Equally significant materials have been gathered at Chichén Itzá.

Mr. Roberts has devoted much time to stratigraphic and analytical work upon the wares of Chichén Itzá.

He has identified a pre-Nahua period, characterized by wares similar to those of the Puuc region; a period corresponding to the time of the Nahua influence in architecture; and a late period during which certain earlier Maya forms returned to favor. His excavations at other sites in northern Yucatán have shown that there exists a still earlier type of pottery, akin to that of the Old Empire cities of the Petén. The historical implications of such findings are obvious. But the investigation has hardly gone beyond the stage of providing hints and indicating hopeful leads for further research. The ceramic study will be continued in conjunction with Mr. Pollock's work on the architecture. For the time being, at least, it will follow the same program. The linked enterprises should yield much information as to the cultural trends and the ethnic movements that led to the establishment of the New Empire cities; and they should also throw light upon the very vexed question of the cultural, and even, by implication, upon the political, relationship between Chichén and other great centers which existed in the peninsula during the centuries immediately preceding the Spanish Conquest. If this can be done, we shall have an invaluable means of checking the accuracy of the Chilam Balam records and of determining how much reliance should be placed upon them as evidence for the correlation of Maya and Christian chronology.

HOUSE-MOUND STUDY

The history of "Nahua" architecture, of Yucatecan architecture, and Yucatecan ceramics are the three most obvious archaeological problems arising from the excavations at Chichén. There are, of course, many others. For example, we know next to nothing as to what Maya "cities" really were. We do not know whether or not they were, in our sense of the word, cities at all. The great groups of religious structures may or may not have been centers of correspondingly large urban populations. Our ignorance of the distribution and the daily life of the common people is abysmal. Much information upon these most important matters can be had from post-Conquest documents, but it should be verified and amplified by study of house, as distinguished from temple, remains. Excavations are needed in the inconspicuous little mounds so abundant at Chichén Itzá, which presumably cover whatever is left of the domestic structures. Intensive surveys of selected areas, such as have been carried out by Mr. Smith at Uaxactún, should also be undertaken at Chichén and elsewhere in the north to determine the density and the distribution of house mounds. As a start toward such a project, Mr. Wauchope has undertaken a study of modern domestic structures in Yucatán and Guatemala.

1.24.

ALFRED V. KIDDER

Division of Historical Research

YB 34:113–115, 1935

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating the rise of native civilization in the New World, its two principal fields being the Maya area in Mexico and Central America and the Pueblo area of southwestern United States. The Section of United States History conducts research upon the growth of Western European institutions in the Americas. The Section of the History of Science strives to bring together and to make available for interpretation the at present widely scattered and coordinated data which bear upon the acquirement and transmission of ordered knowledge.

SECTION OF ABORIGINAL AMERICAN HISTORY

To the panscientific survey which the Section is carrying on in the Maya field there have been added, during the past year, two important new activities, the Copán Project and the Maize Survey.

The Copán Project, under the direction of Mr. Strömsvik, is a joint undertaking of the Government of Honduras and Carnegie Institution, the Institution's share of the expense being covered by a grant from Carnegie Corporation. At Copán, one of the greatest centers of Old Empire culture, the Institution is continuing its effort to conserve and make available for scientific study and lay observation outstanding examples of the architectural and sculptural art of the ancient Maya. The repair of the Temples at Chichén Itzá was done for the same purpose, as was the mending and re-erection, in 1934, of the stelae at Quiriguá. Copán fits well into this program, for its sculptures are not only among the finest ever produced by the Maya, but were also in urgent need of attention, many of them lying so broken and scattered by earthquakes and the impact of falling trees that their beauty could not be appreciated, nor could it be hoped that their fragments would long survive the destructive effects of brush fires and exposure to the weather. Results of Mr. Strömsvik's very effective work during the past season are presented in a later section. Here should most warmly be acknowledged, the invaluable cooperation of the Honduran government, which has provided all labor and free transportation from the border of all equipment and supplies. Furthermore, the Min-

ister of Education, Dr. S. Rodríguez, and President Carias' personal representative, Sr. Carlos Izaguirre, repeatedly visited Copán during the season to confer with Mr. Strömsvik and to see that everything was being done to facilitate the work.

The second new development was establishment of cooperation with the United States Department of Agriculture. Through the good offices of Secretary Wallace and of Mr. Knowles A. Ryerson and Mr. Frederick D. Richey, former and present Chiefs of the Bureau of Plant Industry, the Institution is privileged to have the assistance of Messrs. Collins and Kempton for attack upon the fundamentally important question of the origin of maize and to make studies of the maize agronomy of the Maya area. Maize was the cereal which made possible the rise of pre-Columbian American civilization, but its ancestry is problematical and we do not certainly know where, nor even approximately when, it was first brought under cultivation. Thus we can do little more than theorize regarding the place or the time of the beginnings of the higher New World cultures, including, of course, that of the Maya. And the whole career of the Maya, like that of any farming people, must have been most potently influenced by the agronomic possibilities of the lands they cultivated and by the methods which they worked out for growing their staple crop. Without data upon these subjects, gathered by experts, it is impossible to make reliable estimates of size and distribution of population, or to understand the probable way of life of the ancient people.

The Copán Project and the Maize Survey add to a group of researches which was already extensive. The Division is now active archaeologically in the Mexican states of Yucatán and Campeche; in Guatemala in the highlands of Petén; in Honduras. It has also, in cooperation with Field Museum, been conducting excavations in British Honduras. In addition, it is carrying on, independently or with other institutions, studies of the documentary history of the Maya, ethnological and linguistic investigations in Yucatán and Guatemala, work in human geography in the same regions; as well as gathering data, whenever opportunity permits, upon the climate, geology, health conditions and the botany and zoology of the Maya area.

This heavy and varied program has been undertaken with belief that in any historical study one must utilize the resources of many disciplines and take advantage of all possible side-lights. Our investigation, however, is frankly experimental, in that it still remains to be determined whether or not the practical, and intellectual difficulties of a coordinated panscientific survey can successfully be overcome. Facts, of course, will accrue in abundance. If they be intelligently gathered and clearly set forth, we shall have added significantly

to the sum of recorded knowledge. But shall we be able to digest our masses of raw data in such a way as to reach understanding of the all important whys and wherefores of Maya history, and by so doing contribute toward comprehension of the infinitely complex interaction of those biological, environmental and social forces which govern the evolution of man?

Obviously, synthesis and interpretation should be the ultimate goals of all historical research. Particularly must they be held as objectives during prosecution of such a program as ours. For each investigator is brought so quickly into virgin fields, is confronted with so great a body of intensely interesting and puzzling new material that he runs the constant danger of immersing himself in blindly intensive specialization. And in the same way that the individual worker risks entanglement in detail, with indefinite postponement of the essential process of reaching conclusions, so the program as a whole may easily expand and ramify to such an extent that correlation becomes impossible.

The element of time must also be taken into account. The materials of Maya archaeology are practically inexhaustible. Profitable excavation could go on for a century. Environmental studies, in a region of such diverse topography and climate, might be continued without limit. Furthermore, one of our principal tasks is the gathering of information as to present-day conditions in Central America. This is undertaken to throw light upon the past, and also because the region forms an ideal field for research upon problems of racial and cultural contacts which are of fundamental importance for the modern world. And here again one sees no place to halt our researches, for the present is always with us, change is constantly going on, significant new phenomena develop from year to year.

There is, then, no clearly discernible stopping place for our work, either in space or in time. Certainly the project should be continued for a number of years. There are certain known gaps in our knowledge which must be filled. Many data have to be accumulated before synthesis can become worth while. A considerable period is required to assemble a group whose members can, by practical experience, be brought to see the benefits of close intellectual cooperation and the pooling of information. So, there being no natural termination for our program, it seems necessary to set an arbitrary time limit by establishing a date when each investigation shall come to a close, all findings be recorded, definite conclusions be stated, and formulation be made of problems for future research. Ten years are believed sufficient to permit current researches to be carried to this stage. New projects will only be undertaken if they can be completed within that time. The arrangement will insure that the older

members of the Section's staff shall have completed their work at retirement. And for the younger men it should also be of benefit, for it is good for any student periodically to bring his research to a head, check up, draw conclusions, and make a fresh start.

The above decision implies no doubt on the part of the Chairman regarding the value of the Section's program, nor any feeling that it should be discontinued at the close of the ten-year period. The pause is designed to permit ourselves and our colleagues to judge whether or not the project is so conceived and so prosecuted as to give promise of attaining the historical results for which it was undertaken. The conclusions which we present should also enable the Trustees of the Institution to reach decision as to the nature and scope, of future activities in aboriginal American history.

1.25.

ALFRED V. KIDDER

Division of Historical Research

YB35:111-115, 1936

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating to the rise of native civilization in the New World, its two principal fields being the Maya area in Mexico and Central America and the Pueblo area of southwestern United States. The Section of United States History conducts research upon the growth of Western European institutions in the Americas. The Section of the History of Science strives to bring together and to make available for interpretation the at present widely scattered and uncoordinated data which bear upon the acquirement and transmission of ordered knowledge.

The setting up of the Division in 1929 resulted in simplification of administrative procedure and in the achievement of certain economies. The fundamental purpose of the reorganization was, however, to promote intellectual intercourse between all Institution workers concerned with man's career; and through study of topics of common interest to foster attitude of mind which, it was thought, should lead to clearer formulation of and more effective attack upon the excessively complex problems of social and evolution.

The three groups now functioning as sections of the Division were originally formed for the exploita-

tion of limited and, at first sight, more or less, unrelated fields. The groups, for the most part, are still actively pursuing their own special objectives: But certain elements of the sections' researches are gradually being reshaped or reorientated in such a way as to approach fulfillment of the Trustees' desire for more closely integrated, Divisional program. Thus, the study of the Maya, inaugurated as a purely archaeological project, has been broadened to include consideration of the post-Spanish period, thereby bringing it into direct touch with documentary history. At the same time there have been added to the historical group men with interests in Latin America, whose work serves further to bridge the gap between documentary history and archaeology. Lastly, the Section of the History of Science has assigned one of its members to studies bearing upon the vexed question of the correlation of Maya and Christian chronologies. It is hoped that the above modifications will tend "to widen points of view" and, more specifically, that they may produce a nearer alliance between documentary history and archaeology. The latter end is unquestionably most desirable. Both groups are attempting to reconstruct and to interpret the past of the human race. But history deals with peoples whose stories have been perpetuated by the written word; archaeology with those who have left few or, in most cases, no documentary records. This difference in source materials has led to wide divergence of interest. Historians, because their documents, save those of the last few centuries treat largely of wars and doings of rulers, have perforce concerned themselves for the most part with military and political events. They have accordingly been able to gather relatively little significant information regarding cultural and economic settings. Archaeological evidence, on the other hand, consists exclusively of material remains. Hence archaeologists have become primarily students of culture and are unable, as a rule, even to speculate to the enormously important roles played by individuals, dynasties, national groupings.

Another factor which has hindered association between history and archaeology is the mutual exclusiveness, both geographically and chronologically, of their respective fields of endeavor. Historians devote the lion's share of their attention to recent events in the Mediterranean basin and in West Europe and to happenings still more recent in regions which West European civilization has of late invaded; whereas archaeologists have to do only with the pre-literate past of the Mediterranean and of Europe, with the story of other lands prior to the great European outflow. The historians consider in great detail (because their materials are abundant) a short period and a small area; archaeologists treat more broadly (because evidence is both scanty and expensive to gather) enormous

spans of time and huge terrains. The two disciplines have naturally developed different viewpoints and different methodologies; nor are their findings often readily comparable.

Actual fact-finding as well as judgment regarding the bearing of data upon specific situations must always remain the primary duty of the two specialized groups. But for the carrying out of even such preliminary process as these, both history and archaeology might well profit by association. Archaeology needs the aid of the more mature and experienced historic disciplines in development of better methods for the collection, the ordering, and particularly for the evaluation of evidence. The archaeological record is still so fragmentary that archaeologists, striving to read meaning into it, have tended to reach the stage of reconstructive hypothesis too early. Hypotheses not immediately found fallacious have also too readily been accepted as proven, and search for further pertinent facts has not always been prosecuted with sufficient determination.

While archaeological thinking has doubtless been over-loose, historical reasoning has perhaps gone to the other extreme through reliance so implicit upon the written-word that nothing is taken into account which is not to be found in documentary sources. Furthermore, the average historian has so strong a predilection for what might be called the narrative aspects of his study that he too often neglects the precious incidental fragments of cultural, racial, or environmental information, the historical potsherds, so to speak, that are tucked away in books and manuscripts.

It seems certain that both disciplines could profit from rapprochement not only in the matter of mental attitudes and methodologies, but also through better acquaintance with each other's results. Archaeology can not interpret its findings save in the light of what history shows that men have done under given conditions; history must turn to archaeology for understanding of the prehistoric peoples who laid the foundations of the cultures with which they are concerned.

So while the autonomy of the disciplines should without question be preserved, it is equally clear that mutual understanding and mutual respect should be fostered. And a start toward this highly desirable end can probably most effectively be made by the prosecution of researches in the many fields where history and archaeology overlap and where problems of common interest can be made the object of joint attack.

Such cooperative studies have not often been attempted. The Division's program is therefore to a certain extent experimental. One difficulty which can be readily be foreseen is that of synthesis. Final summation can certainly never be achieved, even in so relatively small an investigation as that of Maya history.

New materials will indefinitely continue to come to light and history is being made from day to day. Events of the coming years may alter radically our interpretation of evidence now in our hands. But correlation of accruing data should nevertheless be a constant and continuing process; and from our facts we should strive to draw inferences which, as President Merriam has indicated, may perhaps serve to sharpen and strengthen contemporary social judgment.

The Division has assumed a heavy task. Consideration of any aspect of man's career brings difficulties of an order far greater than are inherent in any other research. And in organization of such a project one encounters a strange paradox. On the one hand, the vast increase of knowledge, and its inevitable compartmenting by specialized sciences, seems to render reassembly and comprehension well-nigh hopeless. But on the other hand, there is evident throughout the intellectual world a general trend toward unification. Synthesis is becoming, in a way, more readily attainable than ever before. In the past facts appeared to be mutually contradictory. Modern learning, however, shows that all truths are interrelated. Chemistry and physics are striking downward to common fundamentals; zoology and botany are rapidly merging with the resultant newer biology is joining hands with the physical sciences. Similar tendencies are becoming manifest in the human field, where geography, ethnography, sociology, and psychology are constantly drawing more closely together. History and archaeology, although they should more definitely be conjoined than perhaps any two of the above, have not as yet achieved a working alliance. They are not only interdependent, but both can contribute to, and learn from all other groups. If the Division can, by bringing history and archaeology together in a single field, serve to further in any way the development of a better integrated science of man, it will most amply have justified its existence.

SECTION OF ABORIGINAL AMERICAN HISTORY

The archaeological investigations which constitute the Section's major activity are being supplemented, according to a carefully worked-out program, by studies of the environment in which the Maya lived, by researches upon the modern Maya, and upon the documentary history of the post-Columbian period, all of which are designed to render more readily interpretable the necessarily fragmentary archaeological record.

In the correlated undertakings just mentioned, the section has received invaluable cooperation from other departments of Carnegie Institution from many outside agencies, and from individuals. The Department

of Genetics has supported the extremely significant work of its staff member, Dr. Steggerda, on physical anthropology of the living Maya, on Yucatecan agronomy, and on various aspects of present-day Maya life; the experts of the Geophysical Laboratory have given generously of their time to forward Miss Shepard's technological studies of Southwestern and Maya ceramics; the Department of Terrestrial Magnetism has trained the Section's field men in the taking of astronomical observations for determination of the geographical location of ruins, has loaned equipment, and has checked results; the Nutrition Laboratory has made many analyses of Maya foods and Dr. Benedict has collaborated with Dr. Steggerda in publications upon the basal metabolism and the diet of the Maya; the Division of Plant Biology, by kindness of Dr. Shreve of the Desert Laboratory, has made identifications for the Chairman of plant products from ancient dwellings in Arizona and New Mexico.

The University of Michigan biological survey of Central America, carried on at its own expense, is resulting in acquirement of a great mass of information upon the zoology and botany of the Maya area. One result of this investigation is a series of botanical papers, published by the Institution under the editorship of Messrs. Bartlett and Lundell. Duke University, through Dr. Pearse and Dr. Hall, is contributing to knowledge of environment through researches upon the fauna of the inland waters of Yucatán. The United States Bureau of Plant Industry has supplied the services of Messrs. Collins and Kempton, and the United Fruit Company those of Dr. Popenoe, for the investigations upon Maya agronomy and the genetics of maize.

With the University of Chicago there has for some years been in effect an arrangement whereby members of its staff have served as half or part-time employees of the Institution. In this way the Division has benefited by the wise and energetic direction of its ethnological program by Dr. Redfield, Dean of Social Sciences in the University; and has been able to carry on a survey of the Mayan linguistic stock by Dr. Andrade. Also by a part-time arrangement, Miss Shepard, of the Laboratory of Anthropology, has worked on ceramic technology. The Peabody Museum of Harvard University and the Laboratory of Anthropology have supplied quarters to many Division investigators; and the splendid Maya libraries of the Peabody Museum and the Department of Middle American Research of Tulane University have been placed unreservedly at our disposition. Both the last-named institutions and the Museum of the University of Pennsylvania have permitted study and even publication of unique manuscripts.

Contributions by individuals have been of equal importance. Dr. G. C. Shattuck of the Harvard School of Public Health has not only donated his time for

field work bearing upon problems of disease, but has assumed the expense of preparing his medical monographs on Yucatán and Guatemala for the press. Mr. Lawrence Roys has personally defrayed the cost of several trips to Yucatán to study the structural features of Maya architecture; Mr. Ralph L. Roys and Mr. Robert E. Smith, who receive purely nominal salaries, are carrying on key investigations of post-Conquest Maya documents and of Uaxactún pottery, respectively. Lastly, Miss Lila O'Neale, of the University of California, has devoted her sabbatical year research upon Guatemalan textiles.

Scientific activity in foreign countries naturally requires cooperation of governments concerned. In Mexico, Guatemala, and Honduras the Institution has received most effective aid from the authorities: Lic. Toro, Director of the Department of Monuments of Mexico, and Ing. Ignacio Marquina, of the Section of Pre-Hispanic Monuments; Lic. Antonio Villacorta, Secretary of Public Education of Guatemala and Sr. Carlos Villacorta, Director of the Guatemala National Museum; Dr. Jesus Rodríguez, Secretary of Public Education of Honduras, have all striven to facilitate the work of the Institution. The government of Honduras has participated actively in the excavations at Copán, defraying all costs of labor and of the transportation of supplies.

This lengthy statement of cooperations is presented here not only to express the Division's deep gratitude for effective assistance, but also to make clear the many types of relationship, both practical and intellectual, involved in prosecution of so many-faceted a program.

1.26.

ALFRED V. KIDDER
Division of Historical Research
YB 36:135, 1937

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating the rise of native civilization in the New World, its two principal fields being the Maya area in Mexico and Central America and the Pueblo area of southwestern United States. The Section of United States History conducts research upon the growth of Western European institutions in the Americas. The Section of the History of Science

strives to bring together and to make available for interpretation the at present widely scattered and coordinated data which bear upon the acquirement and transmission of ordered knowledge.

SECTION OF ABORIGINAL AMERICAN HISTORY

The year's investigations have yielded an unusual amount of valuable material. Of outstanding archaeological importance were data upon ballcourts and upon the great Hieroglyphic Stairway gathered by Mr. Strömsvik and Dr. Morley at Copán; a remarkable fresco and hieroglyphic inscription were found by Mr. A. L. Smith at Uaxactún; from the Chairman's excavations near Guatemala City came a large collection of pottery, jades, and other mortuary objects from an area hitherto little known. Work upon the living Maya under direction of Dr. Redfield resulted in the rescuing, by Sr. Villa, of much knowledge regarding the fast-fading native culture of the Indians of eastern Yucatán. The historical research was rewarded by discovery of unsuspected documentary riches in the archives of Guatemala.

1.27.

ALFRED V. KIDDER
Division of Historical Research
YB 37:137-141, 1938

The Division of Historical Research comprises three Sections. The Section of Aboriginal American History concerns itself with studies relating to the rise of native civilization in the New World, its two principal fields being the Maya area in Mexico and Central America, and the Pueblo area of southwestern United States. The Section of Post-Columbian American History conducts research upon the growth of Western European institutions in the Americas. The Section of the History of Science strives to bring together and to make available for interpretation that present widely, scattered and uncoordinated data which bear upon the acquirement and transmission of ordered knowledge.

It is the policy of the Division that no new unit of research shall be undertaken until at least the factual results of previous activities in the field concerned have been made of record. A large share of the Division's

energies, during the past year, has accordingly been devoted to the working up of accumulated data and the writing of reports. This has served to direct special attention to problems of publication.

In general, first class factual literature in the social sciences and the humanities is pitifully scanty. In these, as in the natural sciences, the collection and the setting forth of data must precede synthesis and the drawing of conclusions. And because of the bewilderingly faceted life of man and the infinitely wide range of man's doings throughout the ages, in every conceivable type of historical setting, and in all possible sorts of physical environments, the human record must, for the present at least, be largely descriptive. Expression by formula is not feasible, nor can there often be used the condensed forms appropriate for exposition of the regularly repeating phenomena of biology. Publication, therefore, even in the case of the relatively small group of studies with which the Division is occupied, is inevitably voluminous; archaeological papers must carry great amount of illustration. Costs, accordingly, are bound to be heavy; but, on the other hand, it is only fair to point out that acquisition of most anthropological and historical materials is relatively inexpensive, there being little or no call for physical equipment, for laboratories or instruments. However, neither need for much publication nor cheapness of fact finding justifies waste. Also, from the point of view of utility, it is essential that results be thoroughly digested and succinctly stated.

Because of the vast increase in scientific writing of all sorts, as well as because of the rapidly mounting costs of printing, it is certain that present methods for dissemination of knowledge will have to be rather drastically overhauled, those of the disciplines concerning man perhaps most severely of all. How this may be brought about, in the case of its own product, is being given anxious consideration by the Division. Those of its reports which are now well along in preparation will be submitted in forms sanctioned by previous practice. But it is probable that current studies of the situation will result in recommendations looking toward much simplified presentations and considerable reduction in manufacturing costs.

SECTION OF ABORIGINAL AMERICAN HISTORY

The work of the Section in the Maya field consists of archaeological excavation, exploration, and the comparative study of certain particularly important aspects of Maya culture, such as the hieroglyphs, architecture, sculpture, and pottery. The Section also sponsors research in ethnology and linguistics, and cooperates with other agencies in biological, geological, and other

studies designed to throw light on the environment in which the pre-Columbian Maya developed their remarkable civilization, and in which their descendants live today side by side with their Spanish conquerors. Workers in the Sections of Post-Columbian American History and the History of Science, carrying forward investigations in their own fields add to the large body of information being accumulated in regard to the Maya.

As has already been stated, much of the time of the Division staff has, during the period under review, been spent in making the above information available through the writing of reports. Outstanding among several manuscripts so brought to completion are those of Dr. Morley, who has in press his compendious monograph on the hieroglyphic inscriptions of the ruined Maya cities of Petén, the fruit of over 20 years of study; and of Mr. Morris, whose report, embodying the results of his equally long-continued investigations in the very important Basket Maker and Pueblo sites of northern New Mexico and adjacent regions, is ready for the printer. These two monographs will always rank as fundamentally significant contributions to the literature of their respective fields. Progress in working up the results of other activities is noted below.

UAXACTÚN.

Excavation at Uaxactún, in the Department of the Petén, Guatemala, was discontinued in the spring of 1937. This apparently oldest of First Empire Maya cities was under investigation for no less than 11 seasons. Findings of the first years have been recorded by Dr. and Mrs. Ricketson in a volume recently issued (Ricketson and Ricketson 1937). The six years 1932-37 were largely devoted to study of the so-called "Palace," a multi-chambered structure which grew by accretion through a long period of time, and whose thorough dissection by A. L. Smith yielded extremely valuable data upon architectural development and the succession of pottery types. Mr. Smith and E. M. Shook, his associate during most of the work on the Palace, have been engaged, since the close of work at Uaxactún, in preparing the final report upon the general archaeology of the site; while R. E. Smith, assisted by Mrs. Smith, has been studying and writing up, at the Institution's laboratory in Guatemala City, the enormous ceramic collections made at Uaxactún. It is believed that at least 18 months more will be required for completion of these two papers.

KAMINALJUYÚ.

The Chairman's excavations in the mounds and tombs of Kaminaljuyú, near Guatemala City, were also dis-

continued in 1937. The collections, particularly the pottery, throw much light upon the chronological relations between the cultures of the Guatemala highlands, those of the Maya First Empire in Petén, and those of central Mexico. Owing to collapse of the roofs of the tombs, the pottery accompanying the interments was badly broken and crushed. The difficult task of repairing the more than 200 vessels, many of great beauty, and for the most part of types hitherto unknown, was carried out by Mr. Paul Richard of the American Museum of Natural History and Mrs. Harriet S. Cosgrove of the Peabody Museum of Harvard University, whose invaluable services were most generously made available to Carnegie Institution by Dr. Clark Wissler, and Mr. Donald Scott, directors of the above museums. The skill of Mr. Richard and Mrs. Cosgrove served to put the pottery in shape for study, and for permanent exhibition in the National Museum of Guatemala, where it has now been deposited. Each piece was photographed by Miss Barbara Kidder and all outstanding pieces were reproduced in black and white or in water color by the Section's artists, Señores Antonio Tejeda and Victor Lucas. The Chairman spent the winter at the Guatemala laboratory, making notes on the pottery and other artifacts and on the specimens, other than ceramic, from Uaxactún. Mrs. Kidder, who, from the beginning of the Kaminaljuyú operations in 1935, has cared for and catalogued the collections, made, this year, a special study of the large number of jades found in the tombs.

GUATEMALA OFFICE.

In addition to routine archaeological activities, the Guatemala Office, under direction of R. E. Smith, has continued to serve as local headquarters for research workers and visitors from several other institutions: Jeffries Wyman, biologist of the Museum of Comparative Zoology at Harvard; Linton Satterthwaite and J. Alden Mason, archaeologists of the University of Pennsylvania Museum; Theodor Dobzhansky, geneticist of the California Institute of Technology and Carnegie Institution; J. Andrews King, ornithologist of the Field Museum of Natural History; and L. C. Stuart, herpetologist of the University of Michigan. By supplying information, making advance arrangements, securing necessary permits, and attending to the importation of supplies and the exportation of collections, the office is in position greatly to facilitate the work of the scientists who come to Guatemala for special investigations. The Division and Guatemala offices have also made available to the Shell Oil Company and the Fairchild Company all data in their possession regarding the Department of the Petén, where those organizations are carrying on geological and, air-photographic sur-

veys, the results of which will be of much value for the study of Maya archaeology.

ARCHITECTURAL SURVEY.

During the past several years, Dr. H.E.D. Pollock has been engaged in architectural research in northern Yucatán, a field so large and so rich in remains that it has seemed best to treat it by chronological and topographic units. The important area of the Puuc, containing the most abundant and most representative ruins of the so-called "Maya renaissance," has now been explored and Dr. Pollock, has devoted as much time as could be spared from his organization of the Section's photographic files to preparing a report upon them. It is hoped that in this paper methods can be developed for a briefer and more effective presentation of architectural data than has hitherto been attained.

Archaeology of British Honduras.

Mr. J. E. Thompson's work at ruins of San José was begun as a joint project with Field Museum and completed by Carnegie Institution in 1936. San José, a small site, occupied from before the rise of the First Empire to a period apparently only shortly antedating the advent of Mexican influence in Yucatán, is important because it well exemplifies the minor communities, of which great numbers existed, and which must have formed the backbone, so to speak, of the Maya commonwealth, but which have hitherto largely been neglected by archaeologists in favor of the larger, more spectacular cities. Its long occupation also rendered it an unusually favorable place for study of ceramic development. Mr. Thompson has divided his time during the past 18 months between glyphic research and the study and preparation for publication of the archaeological materials from San José. His report on the latter is now in press. He also made a short field trip to British Honduras during the winter of 1938.

GEOGRAPHICAL STUDY.

Information regarding the physical features of the Maya area, its geology, topography, climate, is scattered through a great number of publications: narratives of the Conquest, books of travel, scientific periodicals, government reports. In order to render this indispensable but now relatively inaccessible material available, Dr. O. G. Ricketson, Jr., is making a thorough search of the literature, is preparing an annotated bibliography, and is gathering notes for a general work upon the geography of southern Mexico and northern Central America, suitable for the use of the archaeologist, the ethnologist, and the historian.

PHOTOGRAPHIC FILES.

During the quarter century of the Institution's work in the Maya field there have been accumulated more than 20,000 photographic negatives. These constitute the basic record of every excavation and exploration carried out by the Section. In the early years each investigator assumed charge of the photographs dealing with his own branch of the work. As the Maya project grew, however, it became obvious that a central repository must be established for the safe-keeping and adequate cataloguing of these pictures. A consolidated file was begun at the Section's former administrative office in Washington, but not until general headquarters were established did it become possible to assemble all the material and to secure from the hitherto scattered members of the staff the identifications necessary for accurate labeling.

In 1935 a new uniform system of field recording of photographs was put into operation by Dr. Pollock and during the past two years he has brought order into the great mass of older pictures. With the help of Miss Ritchie his reorganization of the file is now approaching completion. Negatives, contained in fire-proof cases, are arranged serially by years; prints, mounted on cards and bearing negative number and identifying description, constitute a second series in which the photographs are grouped for ready reference by sites and subgrouped in such a way as to bring together all data upon individual buildings, stelae, pottery, etc.

The foregoing activities indicate how large a proportion of the time of the Section's staff was spent, in 1937 and 1938, in laboratory work and in writing. In spite of this several field projects were undertaken. Summary accounts are appended.

1.28.

ALFRED V. KIDDER

Division of Historical Research

YB 38:235-241, 1939

The Division this year completes its first decade. It therefore seems appropriate briefly to review its activities during that period, and to consider the problems, scientific and administrative, which now confront it.

Three groups were brought together in 1929 to form the Division: archaeologists, students of United States history, and investigators of the history of science. As the latter, under leadership Dr. Sarton, were engaged upon the definite task of producing the introduction to the history of science, their activities continued unchanged. The staff of United States historians had been much depleted by retirements; further retirements were imminent. It having been at that time the Institution's policy to concentrate whenever possible upon researches of a type requiring cooperative effort, decision was made to combine resources available for documentary history with those of the archaeological group for a joint investigation in the Maya field.

The Maya Indians of Middle America developed the most brilliant culture of the pre-Columbian New World. Their achievements in sculpture, architecture, economy, mathematics, and hieroglyphic writing rivaled those of the great early civilizations of the Mediterranean, although they had passed their peak before the coming of the Spaniards, they were still a numerous people. Today they form a majority of the population of Yucatán and of Guatemala. The career of the Maya thus offers opportunity for study of several outstandingly interesting phenomena: the rise of a civilization, the growth of a rich complex of the arts, the decay and fall of a culture, the impact of European conquerors of a native people, and the development of biracial communities typical of much of present-day Latin America. These are all of great significance, not only for the understanding of events in this hemisphere but for the light they can shed upon some of the most fundamentally important problems of anthropology and history.

The Institution entered the Maya field in 1914, through support of explorations by S. G. Morley, which during the next few years resulted in discovery of many new sites and in trebling the corpus of Maya hieroglyphic texts. On the basis of the dates contained in the inscriptions, Morley for the first time clearly delineated the major phases of Maya history: the Old Empire, during which Maya culture came into being and spread widely through the southern part of the Yucatán peninsula and adjacent regions; the New Empire, centering in northern Yucatán, where an active renaissance resulted in the erection of such great cities as Chichén Itzá and Uxmal; and finally, the period of invasion, civil war, and consequent decline which took place before the European Conquest.

Being largely based upon a series of bare dates and, for its later parts, upon more or less contradictory legend contained in native and Spanish chronicles, Morley's reconstruction of Maya history needed, he felt, to be checked by the shovel. Furthermore, only by archaeological means could a start be made toward

clothing the chronological skeleton with the flesh of knowledge regarding the ancient life and the arts of the Maya. He therefore selected for excavation three key sites. One of these was Uaxactún, a large ruined city in the Petén jungle of northern Guatemala, discovered by him in 1916; it was, on the basis of the hieroglyphic dates, the oldest and longest-inhabited Old Empire center. The second was Chichén Itzá in northern Yucatán, settled about the close of the Old Empire, occupied through the renaissance, and a leading community, politically as well as ceremonially, during the latter part of the New Empire. The third, Tayasal on Lake Petén, also in northern Guatemala, saw the last stand of a Maya group against European encroachment. This city, founded toward the end of the New Empire by immigrants from northern Yucatán, remained unconquered until after 1690. Investigation of the three sites was designed to provide information regarding the Maya from the dawn to the final fall of their culture.

Work at Tayasal was carried on in 1920 and 1921 with satisfactory results; and in 1924 all available finances and personnel were concentrated upon excavations at Uaxactún and Chichén Itzá.

Chichén Itzá, because of its fine climate and ready accessibility, was made headquarters for research in Yucatán; and until 1935 excavations under Dr. Morley's direction were prosecuted there by E. H. Morris, K. Ruppert, J. S. Bolles, and others. The Temple of the Warriors was cleared, as well as the Caracol, Monjas, Mercado, House of the Phalli, and a number of smaller structures. These yielded a mass of data regarding the architecture, sculpture, fresco painting, and minor arts of the renaissance and the succeeding period when invasions from continental Mexico brought marked religious and cultural changes. All buildings investigated at Chichén were repaired, strengthened, and in some cases partially restored, in order that they might stand as examples of the remarkable architectural achievements of the New Empire Maya.

At Uaxactún the work of O. G. Ricketson, Jr., and A. L. Smith, between 1924 and 1937, produced even more valuable results because, owing to the enormous difficulties presented by the Petén jungles, and the great dilapidation of the ruins, relatively little had previously been learned of Old Empire archaeology. The first important discovery was of a very early building elaborately decorated with colossal grotesque masks in stucco, buried under and perfectly preserved by a later pyramid. After this had been cleared, there were located below and in front of it still older deposits representing hitherto unknown formative stages of Maya civilization which had preceded the Old Empire and which exhibited suggestive relationships with the Archaic cultures of the Guatemalan and Mexican high-

lands. In 1931 A. L. Smith began his seven-year dissection of Structure A-V, which proved to have grown by successive additions and through seven centuries from a group of small units to a great multi-chambered building of the "palace" type. In it were found tombs of various periods; from these and from the buried rooms and courts were collected vessels and potsherds exemplifying the entire course of Old Empire ceramic development, while study of the structure itself brought to light many facts regarding growth of and changes in architectural practice.

Uaxactún and Chichén Itzá were richly productive of materials illustrating the arts and crafts of the Old and New Empires. Study of these materials raised, however, a host of new problems for the most part concerning the chronological and spatial distribution, in other parts of the Maya area, of various cultural and esthetic traits made known by the two excavations. It thus became more and more clearly evident that the archaeological findings, interesting as they were, could not be of maximum usefulness for the reconstruction of Maya history until they could be interpreted in the light of knowledge regarding such environmental factors as geology, climate, water supply, and the faunal and floral resources of the country in which the Maya lived. Nor could ancient life or the ancient religion clearly be visualized solely on the basis of pottery and stone implements, sculptures, and the ruins of temples.

For the desired vitalization of the Maya's past, several non-archaeological sources were available. One of these consisted of the Books of Chilam Balam, writings in the Maya language but in Spanish script, produced by native priests. They embodied histories, prayers, folk stories, medical lore; and they were, at least in part, translations of pre-Columbian hieroglyphic texts. Another rich store of information upon aboriginal conditions was contained in the eyewitness accounts of the conquerors, priests, and earlier colonial administrators. A third and extremely important body of information was to be had from the study of the several million Maya still living in Yucatán and Guatemala, speaking their old tongue, and practicing many of their former arts and even some of their aboriginal religious rites.

So when, in 1929, the organization of the Division led to review of its previous activities and to the making of plans for the future, it was decided to attempt a broader-gauge investigation in the Maya field. The first step in this direction was the addition to the staff of F. V. Scholes, to head a group for research upon the documentary history of the Maya; and of R. L. Roys, for the translation and interpretation of the Books of Chilam and other native literature. At the same time, arrangements were made with the University of Chicago which

permitted the cooperation of R. Redfield for investigations among the present-day Maya.

Thus there were focused upon study of a single people the efforts of workers in the three major disciplines which deal with cultural and social evolution. Although such a joint attack by archaeologists, historians, and ethnologists had long been recognized as desirable, Carnegie Institution was the first to put it into effect with adequate resources and with prospect of being able to carry it forward for a sufficiently long period to determine whether or not it could produce the hoped for results in factual knowledge, in historical interpretations, and, perhaps most important of all, in bringing about the close integration of the social sciences that is essential for real understanding of man's career.

Inaugurated in 1929, the cooperative research upon the Maya was broadened during the next few years in various ways. Study of the Maya group of languages was undertaken by M. J. Andrade; the Institution's Department of Genetics assigned M. Steggerda for work in physical anthropology, human geography, and nutrition; G. C. Shattuck of the Department of Tropical Medicine, Harvard School of Public Health, collected data upon health conditions in Yucatán and Guatemala; J. H. Kempton and the late G. W. Collins of the Bureau of Plant Industry, U. S. Department of Agriculture, R. A. Emerson of Cornell University, and W. Popenoe of the United Fruit Company have made explorations and laboratory studies bearing on the difficult problem of maize origins, as well as agronomic observations in highland and lowland regions. In the all important matter of physical and biological environment much research has been done: in geology by C. W. Cooke of the U. S. Geological Survey; in climatology by R. G. Stone of Harvard's Blue Hill Observatory; in geography by W. and R. A. Atwood of Clark University and the University of Florida; and the University of Michigan has cooperated most effectively by sending to Central America many specialists in zoology, botany, and tropical ecology. A. S. Pearse of Duke University has studied the fauna of the inland waters of Yucatán.

The above researches have been carried on through the thirties. During that period the Division's archaeological activities have to a certain extent been reoriented, in that emphasis has shifted from large-scale excavations at single sites to surveys designed to extend knowledge of the development and distribution of various elements of Maya culture. Thus, K. Ruppert and J.E.S. Thompson have gathered architectural data and hieroglyphic material from hitherto unknown areas lying between Petén and northern Yucatán; H.E.D. Pollock and H. B. Roberts devoted several seasons to New Empire ruins other than Chichén

Itzá, working on architecture and ceramics; R. E. Smith studied the pottery of Uaxactún; and Anna O. Shepard was added to the Division staff for work upon the physical and chemical properties of Maya pottery. F. B. Richardson undertook a comparative survey of sculpture in stone.

Digging, however, continued: at Chichén Itzá until 1935, and at Uaxactún until 1937; and at Copán in Honduras, one of the greatest of Old Empire cities, G. Strömsvik has directed the excavations and the repairs of temples and monuments made possible by the aid of the Carnegie Corporation and the Honduran government. J.E.S. Thompson has excavated in British Honduras; S. K. Lothrop, R. Wauchope, and A. V. Kidder in the highlands of Guatemala.

The above activities have resulted in such a flood of new information that field work, during the past two or three years, has had to be curtailed to allow time for its digestion and for the preparation of reports. This pause has also given opportunity for review and appraisal of the program as a whole. Attempt has been made not only to judge the effectiveness of the Division as a fact-finding agency, but to determine to what extent its work in the Maya field is serving to develop methods for that coordination of the social, biological, and physical sciences without which it seems impossible to reach valid conclusions regarding the history of any people.

In the gathering of data the Division has been without question successful; and such study of results as has so far been possible indicates the direction in which various branches of the investigation should trend. In archaeology, for example, we must still further decentralize devoting less of our resources to large excavations and more to small reconnaissance digs which will aid in delimiting the range of Maya culture and in determining its chronological and cultural relations with other Middle American civilizations. These minor excavations should be supplemented by comparative studies of certain categories evidence which earlier work has shown to be of outstanding significance: pottery, architecture, sculpture, and the hieroglyphic record. In documentary history we should attempt to fill the gap between the relatively well-understood conquest and early Colonial periods and the present, because knowledge of what occurred during the eighteenth and nineteenth centuries is necessary as background for the ethnologists' studies of the modern Maya, and equally essential for the historian who wishes to utilize the ethnologists' results for understanding of times more remote. In ethnology, too, some decentralization would seem desirable, particularly in Guatemala, where conditions being less uniform than in Yucatán, a wider sampling would be profitable.

The enormous field of environmental studies has hardly been touched. On the biological side it is already clear that from the point of view of Maya history the botanical work is of great significance; and that more intimate knowledge of Middle American geology is needed for solution of many problems in ceramic technology, agronomy, water supply, and, in Guatemala, in the relation between volcanic activity and the ancient habitability of large sections of the country.

Materials are pouring in. We are learning what sorts of facts are of most immediate value. We are finding out where and how to get them. These are the easiest parts of the Division's task. Far harder is the interpretive synthesis which is the ultimate goal of the Division's researches, for each investigator is brought go quickly into virgin fields, is confronted with so great a body of intensely interesting and puzzling new material that he runs the constant danger of immersing himself in blindly intensive specialization. In the same way that the individual worker risks entanglement in detail, with indefinite postponement of the essential process of reaching conclusions, so the program as a whole may easily expand and ramify to such an extent that correlation becomes impossible.

The element of time must also be taken into account. The materials of Maya archaeology are practically inexhaustible. Profitable excavation could on for a century. Environmental studies, in a region of such diverse topography and climate, might be continued indefinitely. Furthermore, one of our principal tasks is the gathering of information as to present-day conditions in Central America, undertaken to throw light upon the past and also because the region forms an ideal field for research upon problems of racial and cultural contacts which are of fundamental importance for the modern world. Here again, one perceives no halting place, for the present is always with us, change is constantly going on, significant new phenomena develop from year to year.

Our researches, accordingly, have no clearly discernible limit, either in space or in time. Certainly the project should be continued for several years. There are, as has been shown, certain known gaps in our knowledge which must be filled. However, there being no natural termination for our program, it has seemed desirable to adopt a policy of limited or, perhaps better, stated objectives and to establish approximate time schedules for the various units of research. When each investigation is brought to a close, all findings will be recorded, definite conclusions stated, and formulation made of problems for future attack. This arrangement should ensure that the older members of the staff will not reach retirement with unfinished work on their hands. For the younger men it should also be of ben-

efit, as it is good for any student periodically to bring his research to a head, check up, draw conclusions, and make a fresh start. It is further believed that it would be well for the Division, toward the end of the coming decade, to attempt synthesis of the whole program by producing a history of the Maya based upon a correlation of all branches of the investigation.

The above proposed general stock-taking would permit ourselves and our colleagues to judge whether or not the project is so conceived and so prosecuted as to give promise of attaining the historical results for which it was undertaken. The conclusions which we then present should also enable the President and Trustees of the Institution to reach decision as to the nature and scope of future activities in aboriginal American history.

ARCHAEOLOGY

As was the case in 1937-38, field work in archaeology has been held to a minimum, in order that materials gathered in former seasons may be digested and reports upon them made ready for the press. During the year two of the Division's most important projects have thus been brought to completion: S. G. Morley's many years of research upon the hieroglyphic texts of the nuclear area of the Maya Old Empire through publication of his monumental work *The Inscriptions of Petén*; and E. H. Morris' equally long-continued studies of ancient Pueblo culture, which have resulted in the monograph *Archaeological Studies in the La Plata District, Southwestern Colorado and Northwestern New Mexico*, now in press. As was stated in the last *Year Book*, these two works will always rank as fundamentally significant contributions to the literature of their respective fields.

Notable progress has been made upon the reports dealing with the excavations carried on at Uaxactún between 1931 and 1937 (Ricketson and Ricketson 1937). A. L. Smith, in charge of the Uaxactún Project, devoted the year to correlating the field notes, plans, and photographs, and to writing. In the task of presenting the extremely important results obtained in the complex of superimposed buildings constituting the "Palace," Mr. Smith has been most ably assisted by E. M. Shook, who worked with him throughout this difficult excavation. Mr. Shook is preparing the elaborate plans and sections necessary to make clear the growth of the "Palace."

R. E. Smith worked at the Guatemala office, where the specimens from Uaxactún are being studied prior to their deposition in the Guatemala National Museum. He has nearly completed the classification and description of the enormous and stratigraphically most valuable collection of pottery. He returned to Cambridge

in the autumn to join A. L. Smith in assembling the final report upon Uaxactún. Miss Shepard, also, spent some months in Guatemala making technological observations upon the scores of thousands of sherds recovered at Uaxactún. Her collaboration with Mr. Smith not only has resulted in discovery of many significant facts regarding the pottery itself, but has made possible the development of methods for more effective cooperation between the field archaeologist and the ceramic technologist. The drawings and paintings of Uaxactún pottery have been made by Sr. A. Tejeda, staff artist, and Sr. Victor Lucas.

Dr. Pollock and Messrs. Thompson and Richardson spent the period under review in Cambridge, and Mr. Ruppert was there until he took the field in Mexico in the early winter of 1939.

Dr. Pollock worked on materials gathered during his architectural survey of the Puuc ruins of northern Yucatán. He has superintended Miss Ritchie's work in cataloguing and filing the Division's enormous collection of photographs; and while the Chairman was in the field, he administered the Division office.

Mr. Thompson completed and saw through the press a report upon the excavations at San José, British Honduras, and is now engaged upon a manuscript dealing with the ruins of Benque Viejo, British Honduras. The technological aspects of the San José and Benque Viejo pottery have been studied by Miss Shepard.

Mr. Richardson, who is working on the stone sculpture of Middle America, has finished a paper based on his 1938 reconnaissance in Nicaragua, Salvador, Honduras, and Guatemala. He is at present preparing a summary of what little is known regarding the archaeology of western Honduras.

Mr. Ruppert made progress in assembling the data gathered during his several exploring expeditions to archaeologically unknown areas in Campeche, and also has under way reports on the Mercado, Sweatbath, and other structures at Chichén Itzá which were excavated by him.

Mr. Ricketson has also been at Cambridge throughout the year, continuing his examination of the scattered literature dealing with the geography of Middle America, and preparing a general work upon the physical and biological environment of the Maya area.

The above time-consuming but essential tasks have kept most of the archaeologists at their desks. A certain amount of field activity was nevertheless carried on, the most important of which was the work of Mr. Strömsvik and his assistants at the ruins of the Old Empire city of Copán in southwestern Honduras.

1.29.

ALFRED V. KIDDER

Division of Historical Research

YB 39: 261-264, 1940

The major activities of the Division during the past decade have been study of Maya history and of the history of science, both backward-looking researches the utility of which, in these cataclysmic days, cannot fail to be questioned, both by the men engaged upon them and by those responsible for their administration. Just as we of the staff have been asking ourselves why we are counting prehistoric potsherds, or wrestling with the problem of forced labor in sixteenth century Yucatán, or striving to gauge the influence of Aristotle on medieval physics, so the officers of the Institution must have been wondering whether they are justified in continuing to sponsor the investigation of scientific theories long since outmoded and, even more, why they should promote study of an Indian people whose glory had faded some centuries before Columbus landed and who today are but humble soil-tillers ruled by the descendants of their European conquerors.

Such doubts must trouble all who are now concerning themselves with any but the most urgently practical affairs. Nevertheless, if civilization is to persist, it seems essential that the study of man should go forward and should be broadened and deepened and rendered more precise.

We need, as never before, to know the capabilities and the weaknesses of the human race and to understand the fundamentals of the man-culture relationship, because the mighty machine which science's control of the physical world has permitted us to build exercises its unlimited power for good or for evil only as it is directed by man. That machine, however, now seems in danger of being run for wholly destructive purposes. We are given to thinking of this as something new, but every major invention from the Paleolithic hand ax to the airplane, though at first bringing material benefit has sooner or later created social and economic problems so complex that, lacking sufficient understanding of ourselves, we have, as a rule, been able to solve them only by repeated resorts to the brutalizing and cruelly wasteful expedients of war.

Knowledge of the history of science will certainly not enable us to combat the immediate dangers which menace us. But if the present storm be weathered, how can we hope to build soundly for the future of a world in which the products of science will inevitably play so great a part, if we do not understand their develop-

ment and the effect they have had in the past upon philosophies of life and upon governmental practices? Likewise, though the career of the Maya has even less bearing upon the problems of the moment it gives opportunity for study of the rise and spread of a culture, the dominance of absolute rulers, political rivalries and civil wars, the decline and eventual fall of a virile civilization, submission to foreign military conquest, adjustments between a dense native population and a small class of alien overlords. Such events and such situations have shaped the course of history at all times and throughout the world.

One does not, of course, pursue researches upon the nature of combustion while the house is burning over one's head—one runs for a fire extinguisher. That essential instrument, however, was developed on the basis of physical and chemical knowledge, whereas our comprehension of the physics of the human atom and the chemistry of social and political reactions is so pitifully limited that, in our ignorance, we can do no better than tear apart with war the painfully erected structure of our civilization.

It seems, then, to the historian and the anthropologist that the study of man must at all costs be continued, even though it be long and slow. It cannot be otherwise, because man is so complex a creature, because so much of significance regarding his past can only with the greatest difficulty be recovered, and because the fundamental aims of humanistic research have not generally been grasped nor have the most effective methods for attaining them been worked out. The development of methods has, indeed, always constituted a primary objective of the Institution's historical activities. Dr. Jameson and his colleagues, through their insistence upon thorough and accurate utilization of documentary materials and their rendering available of such materials by publication of archival guides, played an outstanding role in the establishment of sound historical scholarship in the United States. Dr. Sarton has devoted his entire career to the collection and interpretation of data upon the lives of scientific leaders and upon the spiritual and intellectual environments which conditioned their activities. He has put into practice a firmly held belief that the history of science is more than the sum of the histories of individual sciences and that only through synthesis of all positively determinable and pertinent facts can valid conclusions be drawn regarding the all important matter of the growth of scientific thought and as to its effect upon the course of history.

Most recently, the Institution has sponsored a survey of the entire range of Maya history, study supplemented by research upon the varied, environmental factors which throughout the centuries have influenced the career of the Maya and their Spanish conquerors.

This investigation throws light upon events in the pre-Columbian New World. It has even wider bearings upon general anthropological theory. It is also of immediate practical service in bringing greatly needed understanding of present-day conditions in the large parts of Latin America where dense Indian populations have been brought under European control. Yet its greatest value should accrue from the development of methods for comprehensive, coordinated, cooperative research which, if successful in the relatively simple case of the Maya can be perfected and broadened for attack upon the vastly greater and far more complex historical problems which must eventually be solved if we are to attain real knowledge of man in the modern world.

The foregoing is, of course, the special pleading of anthropologists and historians for opportunity, in these rapidly changing and materially minded times, to continue their researches. Research, however, is more than the gathering and recording of facts in the hope that some day someone will be able to make use of them. Synthesis of raw data, the erection and testing of hypotheses should constantly go on, not only in order to avoid useless exploration of blind alleys and to indicate new means of approach, but also to permit the generalizations which are the only form in which the results of specialized investigation can be made really effective through their dissemination to workers in allied disciplines and to the intelligent layman.

The preparation of their product for the essential markets is a matter which should be of special concern to members of an agency, such as this Division, which is devoted to pure research in the humanities. The university historian or anthropologist must put his findings into coherent form, draw conclusions there from, and hand on both summarized facts and conclusions to his students. The museum curator, if he be more than a mere hoarder, does the same in the selection and display of his specimens. But the man who has no stated duties, beyond research is less urgently moved to marshal his materials and has no obvious public beyond a small group of fellow specialists. Yet the data at his command are abundant, fresh, and often highly significant; there is no call upon his time or his energies for routine teaching or museum administration. It would therefore seem that one of the definite objectives of every research man should be the writing of books or articles for a wider audience than is reached by his scientific reports.

ARCHAEOLOGY

The past 12 months have been devoted largely to digestion of the great amounts of new information gathered during the intensive field investigations of the

middle and late thirties. Completion of the resultant reports and work involved in their passage through the press will continue to occupy a considerable amount of staff time during the coming year. Nevertheless, a number of important projects have gone forward. Archaeological explorations in Yucatán were resumed, Dr. Pollock and Mr. Shook spending three months among the little-known ruins of the western part of the peninsula, and Mr. Andrews making a reconnaissance, under very adverse conditions, of an area in Campeche and Tabasco which has hitherto constituted a blank space on the archaeological map. In Guatemala, Mr. A. L. Smith conducted excavations at San Agustín Acasaguastlán in the Motagua valley, discovering two vaulted tombs containing fine examples of the beautiful pottery of the late Old Empire. He also worked out the range of what he has called the Middle Motagua culture, listing well over a thousand mounds of the peculiar San Agustín type. Mr. Strömsvik, assisted by Mr. Lee, continued the excavations and repairs at Copán which Carnegie Institution, with the aid of the Honduran government, has been engaged upon since 1936. During the past year, Mr. Strömsvik completed resetting of the great Hieroglyphic Stairway and cleared of debris and consolidated the walls of two temples flanking the ballcourt. Mr. Shook, in addition to his work with Dr. Pollock in Yucatán and with Mr. Strömsvik at Copán, accompanied Mr. A. L. Smith to Uaxactún to make observations needed for completion of the report upon that site. He also surveyed a previously unmapped section of the Kaminaljuyú ruins and made a brief reconnaissance of the ruins of Rabinal. Dr. Brainerd has been working upon the collections of Yucatecan pottery in storage at Chichén Itzá, and Miss Shepard has continued her researches in ceramic technology.

Progress upon reports has been notable. Dr. Morley and Mr. Roys have brought nearly to completion their study of the Xiu family, rulers of Uxmal, and of their descendants to the present day. Messrs. A. L. and R. E. Smith have continued work upon a large monograph dealing with the excavations at Uaxactún. Other monographs are in preparation by Dr. Pollock on the architecture of the Puuc region of Yucatán, by Mr. Ruppert on explorations in Campeche, by Mr. Richardson on the antiquities of Honduras, by Mr. Thompson upon excavations in British Honduras and upon a study of prehistoric Middle American deities, and by the Chairman upon the Kaminaljuyú mounds near Guatemala City.

During the year the Institution's field station at Chichén Itzá, occupied since 1923, has been given up and Dr. Morley has established headquarters in the outskirts of Mérida, where space is available for storage of Division equipment and the ceramic collections.

In January President Bush, President Keppel of Carnegie Corporation, Mr. Shepley, Chairman of the Trustees' Committee on the Division of Historical Research, and Dr. Jewett and Senator Walcott of the Institution's Board of Trustees visited Guatemala and Honduras. The work done by the Institution at Quiriguá was inspected, and two days were spent at Mr. Strömsvik's excavations at Copán, where a conference was held with Dr. Rodriguez, Minister of Public Education of Honduras. The party then proceeded to Guatemala City, saw the Division's laboratory there, and made a tour of the highlands to acquaint themselves with the Indian towns being studied by Drs. Redfield and Tax. With Dr. L. H. Adams, Director of the Geophysical Laboratory, and Dr. F. E. Wright, a journey was made to the camp on the young volcano, Santiaguito, where Dr. Zies is directing research upon volcanological and magnetic problems. After the return of Drs. Bush, Keppel, and Jewett to the United States, Senator Walcott, Mr. Shepley, and the Chairman went to Yucatán and visited Dr. Morley at Chichén Itzá.

I.30.

ALFRED V. KIDDER

Division of Historical Research

YB 40:289-292, 1941

The devastating ill wind which the present international situation has set blowing across the world has had at least one happy result in bringing the nations of the Western Hemisphere closer together. We of the United States and the peoples of Latin America, being equally the cultural offspring of the Old World, have naturally sought overseas for intellectual, spiritual, and artistic contacts; both we and they have confined our foreign travel almost exclusively to Europe. The result has been a most lamentable ignorance of each other's countries and of each other's ways of living and thinking. Americans (to use, for want of any other, a term whose calm assumption of sole occupancy of two continents is quite reasonably distasteful to our southern neighbors) are even more remiss in this regard than citizens of the Latin republics. So it is well that, albeit tardily, there have come realization that we share with them a common destiny, and recognition of the fact that only through fuller knowledge can there

be achieved the mutual understanding and mutual respect necessary for a united stand in defense of New World ideals.

Scientific institutions can play a most effective part in fostering friendship between the Americas. They have no political objectives, they seek no commercial advantage. Their research workers import nothing but a great curiosity about nature and man, they export only facts. Their findings are given freely to all who wish to make use of them. And, most important of all, they are coming to cooperate more and more closely with governments and universities for attack on problems of common interest. It is impossible to exaggerate, to cite the most outstanding example, the contribution to good will toward the United States that has been made by the Rockefeller Foundation through its medical researches.

The Carnegie Institution of Washington has, for many years sponsored studies in Latin America dealing with almost every major branch of the physical, biological, and social sciences. The Institution's Division of Historical Research has, during the past two decades, devoted its major effort to work in Middle America. As stated more fully in earlier reports, its aim has been to gain knowledge of the pre-Columbian civilizations, of colonial and republican history, and of life in the modern societies formed by the welding together of Indian and European elements. Only by thus combining researches in archaeology, documentary history, and ethnology, together with supplementary studies of the environment, can adequate understanding, it is felt, be had of present-day conditions.

In its work in the Middle American republics, the Division has operated under governmental contracts, and has cooperated actively with native scholars. Two of its investigators are Mexican citizens; another is a Guatemalan, as is its staff artist. In Honduras, the Division has been entrusted with the expenditure of the funds, which, dollar for dollar, the government of that country has matched with those of the Institution, for the excavations at Copán.

In addition to, its purely scientific objectives, the Division has striven to preserve and make permanently available for scholars, students of art, and the native and traveling public the most important architectural and sculptural remains of the ancient Maya. At Chichén Itzá in Yucatán, at Quiriguá in Guatemala, and at Copán in Honduras, work of this type has been carried on, generously aided by grants from the Carnegie Corporation of New York.

During the period covered by the present report (July 1, 1940 to June 30, 1941) archaeological investigations went forward in Mexico, Guatemala, Honduras, Salvador, and Nicaragua. Drs. Redfield and Tax continued the ethnological survey of highland Guate-

mala; Sr. Villa, that of Maya-speaking tribes in Mexico. Mr. Scholes and his associates of the Section of Post-Columbian American History worked in Washington on materials gathered during former years.

The Division and American scholarship suffered an irreparable loss in the death, on January 26, of Dr. Manuel J. Andrade. Born in Spain in 1885, Dr. Andrade was educated at the Instituto Regional of Coruña, and came as a young man to the United States, where he held various positions as a teacher of Romance languages. Becoming interested in the scientific aspects of linguistics, he studied under Dr. Franz Boas and received the doctorate from Columbia University in 1929. In the following year, he accepted a joint appointment as Associate Professor at the University of Chicago and Staff Investigator of Carnegie Institution. Half Dr. Andrade's time was devoted to teaching advanced students in linguistics and half field work and research on the languages of the Maya stock. He made many trips to Mexico and Guatemala, amassing enormous amounts of material concerning Yucatecan Maya, Huastec, Quiché, Tzutujil, Cakchiquel, Pokoman, Mam, and other tongues. In the course of this work he developed remarkably effective means for the mechanical recording of speech. At the time of his death a compendious monograph on Yucatec was nearly complete. In this work, which is being made ready for publication by his former secretary, Mr. S. L. Bradshaw, Dr. Andrade utilizes new methods of linguistic analysis. It is believed that the work will not only be of great value to Maya students, but will also constitute a highly significant contribution to linguistic science. Dr. Andrade's materials on the other Maya languages were collected with such painstaking accuracy and recorded with such characteristically meticulous care that they can readily be utilized for continuance of the research which he so brilliantly inaugurated.

The only change in the personnel the Division has been caused by the much regretted resignation of Mrs. Walter Edwards, who since 1931 served faithfully and efficiently as Division Accountant. She has been succeeded by Mrs. Douglas Tepper.

ARCHAEOLOGY

As stated above, archaeological work has been done during the past year in five Middle American republics. In Yucatán, Dr. Sylvanus G. Morley excavated at the ruins of Uxmal, clearing a masonry platform on which were fragmentary remains of a number of stelae and assembling the pieces for study and photography. He also recovered several hitherto missing bits of two large stone rings (comparable in function to basketball goal rings) which had fallen from composite walls of a ballcourt. The special interest attaching to

these rings, parts of which have been known for many years, is due to their bearing very important calendrical inscriptions.

Mr. Joseph Lindon Smith, outstanding painter of ancient sculptures, particularly those of Egypt, repeated his visit of 1940 to Yucatán, where he produced a further series of canvases of reliefs and carvings in the round. As in 1940, Mr. Smith presented these invaluable records of Maya art to the Carnegie Institution, which, in turn, will distribute certain of them to museums in Mexico and the United States.

Dr. George Brainerd was in Yucatán until February, finishing his observations on the pottery collected during past years from various parts of the peninsula. Since then, he has been at Division headquarters in Cambridge, preparing a report on Yucatecan ceramics.

In Guatemala, Mr. A. Ledyard Smith excavated in one of several narrow, rectangular, earth-walled enclosures occurring at the Kaminaljuyú site. Although their function was unknown, it was suspected that they might be remains of ballcourts. Trenches dug by Mr. Smith proved this to have been the case. The Chairman also worked at Kaminaljuyú, making a surface study of its nearly 200 mounds. Mr. Robert E. Smith was in Cambridge for about half the year, preparing the final report on the pottery of Uaxactún. On his return south in January, he resumed direction of the Guatemala office and laboratory.

In Honduras, Mr. Gustav Strömsvik, assisted by Mr. Robert F. Burgh, Mr. Arthur W. Wheelwright, and, as a volunteer, Mr. Leonard J. Currie, Fellow of the Harvard Architectural School, completed the excavation and repair of the temples adjoining the Copán Ball Court. He also reset the displaced elements of the so-called Venus mask panel, which surmounts the Jaguar Stairway. During the season, Mr. Strömsvik continued the installation of specimens in the Copán Museum; and Mr. Burgh aided the local authorities in completing an aqueduct which will, for the first time, provide the town with a supply of running water.

During the year, the Division has extended its archaeological investigations to Salvador and Nicaragua. In the former country, excavations west of the city of San Salvador were inaugurated in 1940 by Mr. John M. Dimick under the auspices of the Middle American Research Institute of Tulane University. At the close of that season, the Division was invited by the University, at Mr. Dimick's suggestion, to cooperate; and when reorganization of the Middle American Research Institute compelled its withdrawal from active field work, Mr. Dimick, who finances and directs the undertaking, requested the Division to continue its association therewith. This offer, giving opportunity to keep in close touch with research in a highly important and hitherto next to unknown area, was gladly accepted, and

all members of the Division staff who were in Central America profited by visits to the excavations and by discussion of the problems involved. The work has revealed a most interesting sequence of unexpectedly large buried structures, study of which is yielding invaluable information as to architectural and ceramic developments.

In Nicaragua the season's activities demonstrated anew the fact that, in archaeology, the unforeseen always happens. Mr. Francis B. Richardson went to Nicaragua to examine, as part of his study of Middle American sculpture, certain carved monuments mentioned in the literature. In preparation for his visit he had read all available accounts of previous exploration and he noted references to human footprints found many years ago in a deeply buried volcanic stratum just west of Managua. On arrival at Managua, Mr. Richardson made inquiries regarding the foot prints, and learned that quarrymen had recently uncovered new examples. He was taken to the site, recognized the importance of the tracks, and undertook a series of excavations which, occupying the entire season, effectually prevented any attention's being given to the sculptured monuments.

1.31.

ALFRED V. KIDDER

Division of Historical Research

YB 41:247-248, 1942

Well before the entry of the United States into the war it had become evident that the general financial situation along with the rapidly expanding defense activities of the Institution would sooner or later necessitate curtailment or deferment of customary and normal research programs. The Division's 1941-42 program was accordingly formulated with a view to gathering as great an amount of raw data as possible in order that members of the staff not in war service might be able profitably to pursue their studies, for a relatively extended period, with a minimum of expense for field work. The season therefore opened earlier than usual, and when hostilities broke out, several parties were already in Central America and others were on the point of departure. Inquiry as to further procedure brought instructions from the Institution headquarters that original plans should be followed; and, later, the United

States legations in the countries concerned requested that undertakings having value in supplementing the Government's program of Inter-American cultural relations be continued. All scheduled explorations and excavations could thus be carried to completion. When the Axis submarine campaign was extended to the Gulf of Mexico and the Caribbean, however, it was decided that irreplaceable specimens and notes should not be exposed to the risks of ocean transportation. Hence Messrs. R. E. and A. L. Smith, Strömsvik, Shook, Ruppert, and Richardson are remaining in Central America to work up their materials.

An unusually large number of excavations were undertaken. In Yucatán, Dr. Morley cleared the elaborately decorated façade of a buried temple at Uxmal; Messrs. Brainerd and Andrews worked at Mayapán, Acanceh, and other ruins in the northern part of the peninsula, gathering ceramic and architectural data which will be of much value in interpreting the later prehistory of that region. In Guatemala, the investigation of the great archaeological site of Kaminaljuyú in the outskirts of Guatemala City was continued. Mr. Shook completely excavated a large mound, which proved to contain a superposition of four structures, and three tombs, one of them the richest in pottery and jades so far found at Kaminaljuyú. Mr. A. L. Smith worked on three of the several rectangular courts in which the ancient ceremonial ball game was played. These yielded a number of fine stone sculptures, mostly serpent and parrot heads with human faces in their open mouths. The Chairman devoted the season to preliminary study of the great amounts of pottery recovered by Messrs. Shook and Smith.

In Honduras, Mr. Strömsvik carried into its eighth year the program of excavation and preservation of the ruins of Copán, sponsored jointly by the Government of Honduras and Carnegie Institution. He completed the repair of Temple II, now known, because of the long hieroglyphic texts adorning its walls, as the Temple of the Inscriptions. He also discovered south of the Acropolis an area containing numerous graves. As these held a great many mortuary vessels, representing several periods, his collections will throw much light on the local sequence of pottery types.

The excavations at San Andrés, El Salvador, directed by Mr. John Dimick were not pursued this year because of Mr. Dimick's entry into war service, his assistant, Mr. S. H. Boggs, remained in Salvador to make a photographic record of the many large private collections of archaeological specimens in that country. Correlated with the Division's program was a survey of eastern Salvador by Mr. John M. Longyear, of the Peabody Museum of Harvard University, a project carried out under the auspices of the Institute of Andean Research with funds provided by the Coordinator of

Inter-American Affairs. The Chairman served as director and visited Mr. Longyear several times in the field. The latter made a reconnaissance of the country east of the Lempa River, locating and mapping a large number of sites. He also excavated a small ruin at Los Llanitos, south of San Miguel, which proved to contain an interesting ballcourt, the southernmost yet recorded. Mr. Longyear's report will be issued by the Peabody Museum.

In Nicaragua, Messrs. F. B. Richardson and Karl Ruppert continued the investigation at El Cauce, near Managua, where in 1941 Mr. Richardson discovered human footprints in a deeply buried layer of consolidated volcanic mud [Chapter 32.1 this volume]. The footprints were followed for several meters farther and a protective structure was erected over them. Mr. Ruppert devoted the season to study of archaeological remains in the recent deposits overlying the volcanic strata. Final judgment as to the antiquity of the footprints must await the working-up of Mr. Ruppert's materials, further research on the volcanology of the region, and paleontological studies bearing on the age of certain animal tracks found by Mr. Richardson.

No field work in ethnology or linguistics was undertaken, as Drs. Redfield and Tax and Messrs. Villa and Rosales were engaged in preparing reports on earlier investigations, Dr. Abraham M. Halpern joined the staff in 1941 to continue the study of Maya languages which was interrupted by the death of Dr. Andrade. Dr. Halpern, however, has been granted leave of absence for war service.

Researches in the history of science and in documentary history have gone forward, Drs. Sarton and Pogo, working in Cambridge, Dr. Stock in Washington, and Scholes and Miss Adams in Albuquerque, where Mr. Scholes, also conducted a course in methods of archive study at the University of New Mexico. Dr. Chamberlain is on leave of absence, acting as Senior Cultural Assistant in the United States Legation at Guatemala City.

During the year the Division lost, through resignation, the services of Dr. Oliver G. Ricketson, Jr., a valued member of the staff since 1922. Dr. Ricketson accompanied Dr. Morley on several journeys of exploration in the Petén; he was in charge of the initial excavations in Northeast Colonnade and the Caracol at Chichén Itzá; he investigated the ruins of Baking Pot, British Honduras; he inaugurated and for several years directed the extremely important excavations at Uaxactún in the heart of the Petén jungle. Dr. Ricketson's ability as an organizer and leader of expeditions into difficult country and to his skill as a field archaeologist, is due a very large share of our present knowledge of the Maya Old Empire.

1.32.

ALFRED V. KIDDER

Division of Historical Research

YB 42:177–178, 1943

During the past year the Division has undertaken no archaeological exploration or excavation, nor is it probable that activities of this sort can be resumed for some years to come. Not only has field work been suspended, but many members of the staff—archaeologists, ethnologists, historians—are now, or soon will be, in the armed forces or engaged in other activities connected with the war. Hence no fresh archaeological data are coming in. Moreover, the men in service, are of course unable to complete reports on investigations in progress at the outbreak of hostilities. Among them are several of particular importance: H.E.D. Pollock's architectural survey of Yucatán; G. W. Brainerd's and J. M. Longyear's studies of the pottery of Yucatán and Copán; G. Strömsvik's excavations at Copán; and A. L. and R. E. Smith's work at Uaxactún. The research of A. M. Halpern on the Maya languages has also been interrupted, as have the studies by R. S. Chamberlain on the history of the conquest of Yucatán.

ACTIVITIES, 1942–43

During the period under review several members of the Staff and associates have entered war service. H.E.D. Pollock is an officer of the Army Air Corps on duty in North Africa. K. Ruppert is overseas with the American Field Service. R. E. Smith is working with the United States military attaché in Guatemala. G. Strömsvik is in the Norwegian Navy; G. W. Brainerd and E. W. Andrews are in that of the United States. R. S. Chamberlain is Senior Cultural Assistant in the United States Embassy in Guatemala. A. M. Halpern is giving instruction in Japanese at the University of Chicago. Others have been engaged in the writing of reports: S. G. Morley on the hieroglyphic inscriptions, A. L. Smith on the excavations at Uaxactún, J.E.S. Thompson on those at El Baúl, E. M. Shook and A. V. Kidder on those at Kaminaljuyú, Anna O. Shepard on Plumbate pottery, Tatiana Proskouriakoff on Maya architecture and sculpture, E. H. Morris on excavations in Colorado, F. V. Scholes and R. L. Roys on various aspects of Yucatecan history. S. L. Bradshaw has continued preparation for the press of the exhaustive study of Maya grammar left unfinished at the death of M. J. Andrade.

Before entering service, Mr. Strömsvik returned to Copán to make arrangements for storage of Institution

equipment and for supervision of the ruins and museum by the Government of Honduras. Mr. Shook, who is temporarily remaining in Guatemala, has had opportunity to carry out certain minor explorations. He has also studied local museum and private collections and has investigated several finds of archaeological material made in the course of road and airfield construction and by private individuals. Most notable of the latter was a cache of Plumbate vessels and a gold plaque unearthed near Quezaltenango by Sr. Vitalino Robles, who most generously made these very important specimens available for study.

F. B. Richardson was obliged, for reasons of health, to postpone further work on the problem of the deeply buried human footprints near Managua, Nicaragua. He is now in South America, making observations on monumental stone sculpture for comparison with that of the Maya area. S. H. Boggs completed the photographing of several large collections of pottery in Salvador and has also been preparing a final report on the excavations at Campaña San Andrés, which were financed and carried out by Mr. John Dimick under the auspices of Carnegie Institution.

1.33.

ALFRED V. KIDDER

Division of Historical Research

YB 43:167–169, 1944

Because several members of the staff are serving in the Army and Navy or are engaged in other activities connected with the war, and because those not so engaged have been occupied with the preparation of reports, little field work has been done in Middle America. The Division has therefore been unable to meet in full the terms of its contracts with the governments of Mexico, Guatemala, and Honduras, which call for the annual expenditure of stated sums. The authorities in those countries, however, in the fine spirit of cooperation they have shown in all dealings with the Institution, have agreed to waive all financial requirements for the period of the present emergency. In the meantime the limited amount of field work that it has been possible to carry on, together with results of laboratory and archive research and study of data accumulated in former years, has permitted clearer formulation of problems to be attacked when full-scale activity can be resumed.

ACTIVITIES, 1943-44

During the period under review the several members of the staff and associates engaged in the war effort have continued their service. Major H.E.D. Pollock, of the Army Air Corps, has been on duty in Italy since the invasion of that country. Mr. Gustav Strömshvik, of the Royal Norwegian Navy, after a year with the North Atlantic convoys, was transferred to an English base and took part in the original landings on the coast of Normandy. Lieutenants (j.g.) G. W. Brainerd and E. W. Andrews have been serving in the Navy overseas, the former in India. Mr. Karl Ruppert, a volunteer in the American Field Service, drove an ambulance with the British forces throughout the recent campaign in Burma. He has now been transferred to the Italian front, where during the last war he served with the United States Army Medical Corps. Miss Eleanor W. Ritchie, secretary of the Division, is an ensign in the WAVES, on duty in Washington.

In civilian capacities, Mr. R. E. Smith, after nearly two years as assistant to the United States military attaché in Guatemala, returned to the Division in June 1944. Mr. E. M. Shook has been engaged in the production of quinine in Guatemala. As his work took him to all parts of the Pacific slope of the Guatemala highlands, a region of great archaeological importance but one very little known, he was able to locate a large number of new sites, as well as to observe and photograph many private collections of antiquities. Dr. A. M. Halpern has continued as instructor in Japanese the University of Chicago, Dr. R. S. Chamberlain as senior cultural assistant in the United States Embassy in Guatemala. Mr. F. B. Richardson has been serving as legal attaché at the Embassy in Ecuador.

Dr. S. G. Morley spent part of the winter vacation compiling a card file of the Maya hieroglyphs carved on stone. In company with Mr. J.E.S. Thompson, he later visited archaeological sites in Chiapas, Mexico, returning to Yucatán by way of the Pasión and Usumacinta rivers. A report on these journeys appears below. Mr. Thompson, before and after the Chiapas trip, was in Mexico City studying the rich collections in the Mexico National Museum and conferring with the very active and able group of archaeologists headed by Dr. Alfonso Caso, of the Instituto Nacional de Antropología e Historia. The members of the Instituto have been most cordial and cooperative, sparing no pains to render visits of the Division staff to Mexico City pleasant and profitable. In particular, Professor I. Marquina, acting director of the Instituto during the service of Dr. Caso as Rector of the University of Mexico; and Professor E. Noguera, director of the National Museum, have been unremittingly helpful.

In September 1943 the Chairman attended the third round-table conference sponsored by the Anthropological Society of Mexico. These conferences, the first of which was devoted to the relationship of the Tula and Teotihuacán cultures, the second to the mysterious La Venta or Olmec culture of the Gulf Coast, have served not only for the exchange of information and the formulation of scientific problems, but also to promote close personal relations between the archaeologists of Mexico and the United States, many of the latter having attended each of the round tables. That of 1943 concerned the prehistoric relations between the cultures of Mexico and those of southwestern and southeastern United States. At its conclusion the Chairman, with Dr. Isabel T. Kelly and Dr. Emil Haury, visited museums and private collections in Morelia and Jalisco and conferred at her laboratory in Guadalajara, with Dr. Kelly, who, under a joint grant from the American Philosophical Society and Carnegie Institution, is devoting the current year to preparation of reports upon her very important excavations and surveys in Western Mexico.

In April and May 1944 the Chairman was in Central America, spending several weeks in Salvador studying collections in the National Museum and observing the excavation of Tazumal, which is being carried on by Mr. S. H. Boggs for the government of that country; and, in Guatemala, studying collections and conferring with Messrs. R. E. Smith and E. M. Shook. At that time there was planned an exhibit of the very beautiful paintings by Sr. Antonio Tejeda F. of pottery found by Mr. Strömshvik at Copán. This was later held at the Instituto de Bellas Artes in Guatemala City, was largely attended, and received much favorable comment in the press. Such exhibits, of which several have been held in former years, serve to arouse local interest in the preservation of antiquities and to promote understanding of the aims and methods of the Institution's work in Middle America. Similar results have been achieved by Dr. Morley's frequent lectures in Mexico and Guatemala and by those of Mr. Strömshvik in Honduras.

During the year Dr. Sol Tax directed the food survey of Guatemala and, in cooperation with the Instituto de Antropología e Historia, directed a cooperative ethnological project in Chiapas. He devoted a third of his time to teaching at the University of Chicago.

Sr. Alfonso Villa R. taught from March to November 1943, a course in ethnographic methods at the Escuela Nacional de Antropología e Historia (Mexico City), while gathering to together the materials obtained in the Tzeltal community of Oxchuc (Chiapas) the previous year. In December he returned to the same community for six months, accompanied for two months by four of his students in the Escuela. Upon

his return to Mexico City in June 1944, he began to bring together all his data of the two season (and those of his students) into a monograph on Oxchuc. He also accepted an invitation to resume teaching at the Escuela Nacional for four months of the year.

Advantage has been taken of the lull in field activities to make progress with the writing of reports and with their preparation for press by Mrs. M. W. Harrison, editor of the Division. Dr. F. V. Scholes and Mr. R. L. Roys have worked on their joint monograph on the history of the Acalán-Tixchel area, Mr. A. L. Smith on that concerning the excavations at Uaxactún. Mr. J.E.S. Thompson's report on El Baúl has been completed, and that of Miss A. O. Shepard on Plumbate pottery is nearing that stage, as are those of Mr. E. H. Morris on his work on the early cultures of northeastern Arizona, and of the Chairman in collaboration with Mr. E. M. Shook and Dr. J. D. Jennings on Kaminaljuyú, Guatemala. Miss T. Proskouriakoff's album of restored drawings of Maya temples and groups of buildings is now in press. It is believed that, in addition to its value to Middle Americanists, this work will be of much interest to students of Old World archaeology and to architects. During the year Dr. Tax continued preparation of his Panajachel (Guatemala) materials. Publication of his monograph on the economy of the Indians, now completed, was held in abeyance, and his comprehensive volume on the mental culture, which is nearly finished, was laid aside, while he worked on a short introductory volume about the community as a whole. This book should be near completion by the end of 1944.

writing of reports, As a result, the Division's investigations have been brought nearer to the stage of definitive publication than at any previous time.

With great regret we record the passing of two persons formerly connected with the Division, Ann Axtell Morris and George Clapp Vaillant.

Mrs. Morris, who possessed great abilities as a writer and an artist, was entrusted by her husband, Earl H. Morris, with the copying of the extremely important frescoes discovered by him during the excavation of the Temple of the Warriors at Chichén Itzá, and was co-author of the monograph on that building. In later years she assisted Dr. Morris on his many expeditions in Arizona and New Mexico, making a specialty of the recording and study of pictographs. Her two books, *Digging in the Southwest* and *Digging in Yucatán*, which have had a large sale that still continues, have done much to acquaint the public with the methods and aims of archaeology.

Dr. Vaillant, formerly with the American Museum of Natural History and at the time of his death Director of the Museum of the University of Pennsylvania, was a member of Dr. Morley's staff at Chichén Itzá in 1926. During that season he excavated the Temple of the Initial Series and, at the Temple of the Phalli and elsewhere, made stratigraphic studies which laid the foundation for subsequent ceramic research in Yucatán by H. B. Roberts and G. W. Brainerd. Dr. Vaillant's work for the American Museum on the early cultures of Mexico was a brilliant scientific achievement, and, like Mrs. Morris' books, his *Aztecs of Mexico* has done much to promote an intelligent interest in archaeology. Throughout his career he kept closely in touch with the Division's work, giving freely of his time to visit our excavations and advise with us as to problems of mutual interest.

L34.

ALFRED V. KIDDER

Division of Historical Research

YB 44:163-166, 1945

Now that the war is over, several members of the staff who have been serving in the armed services or in other forms of war work are expected soon to return, and it is hoped that in the near future some at least of the interrupted activities of the Division may be resumed. Indeed, during the past year it has been possible to undertake a limited amount of archaeological and ethnological field work. Most staff members not in service, however, have devoted themselves to the

ACTIVITIES, 1944-45

Major H.E.D. Pollock, after three years, with the photographic division of the Air Corps in North Africa and Italy, returned late in 1944 for duty in Washington, and has recently been accorded inactive status. He will resume his studies of Maya architecture in the autumn of 1945. Mr. Gustav Strömshvik enlisted in 1943 in the Royal Norwegian Navy. He served on the North Atlantic convoys, took part in the invasion of Normandy, and, since the landings there, has held an administrative position at Norwegian headquarters in Edinburgh. He has recently been discharged. Mr. Karl Ruppert, volunteer in the American Field Service, was with the British Army during the Burma campaign and later in Italy. In the spring of 1945 his unit was transferred to northern Europe, where it was engaged until the end of hostilities in the evacuation of

wounded and in helping to clear captured concentration camps. He has now resumed his position with the Division. Dr. G. W. Brainerd, who holds the rank of lieutenant in the Naval Reserve, is attached to the Special Services Division of the Office of Research and Invention. His duties have taken him to India, Ceylon, and China. Miss Eleanor W. Ritchie, secretary of the Division, is a lieutenant (j.g.) in the Naval Reserve, on duty in Washington.

In civilian capacities, several members have taken part in the war effort. Mr. E. M. Shook is in charge of the large quinine plantation of El Porvenir in Guatemala. In the course of this work he has been able, as in past years, to make valuable observations on sites in a region hitherto very little known archaeologically and to obtain photographs of monuments and of objects in private collections. Dr. A. M. Halpern has continued as director of the language program in the Civil Affairs Training School at the University of Chicago. Dr. R. S. Chamberlain, senior cultural assistant in the United States Embassy in Guatemala, has had opportunity, during his four years at that post, to foster the close international intellectual relations which, we believe, have been a not unimportant by-product of the Division's more than three decades of activity in Mexico and Central America. He expects to resume his historical studies in the near future. Mr. F. B. Richardson, in 1944 legal attaché at the Embassy in Ecuador, attended the conference at San Francisco as adviser on Latin American affairs.

Dr. S. G. Morley, spent the winter in Yucatán, continuing his research on the Maya hieroglyphs. He has been in constant touch with Sr. Alfredo Barrera Vásquez, whose translation and correlation of variant historical and ceremonial Maya texts, the so-called Books of Chilam Balam, were carried on in 1943-44 under a grant from the Rockefeller Foundation administered at the Foundation's request, by Carnegie Institution. Mr. R. E. Smith continues in charge of the Division's office in Guatemala City. During the past winter, he was informed that road work at Cobán in Alta Verapaz had exposed a prehistoric midden. This he excavated, recovering a large collection of clay figurines and pottery fragments, many of the latter of a very beautiful incised ware of which only a few pieces had previously been known. Mr. Smith has also devoted much time to the installation of the archaeological collections in the Guatemala National Museum, which, under the directorship of Sr. Flavio Rodas, is being transferred to new and larger quarters. As chairman of the advisory committee on the museum, he has been assisted by Sr. Antonio Tejeda, artist of the Division, and Sr. Antonio Goubaud.

Sr. Tejeda continues to produce meticulously accurate and beautiful paintings of Maya pottery. Al-

though only a relatively small proportion of these can at present be used as illustrations in the Division's publications, it has been our policy to have such reproductions made of all important pieces from our own excavations and of those in museums and in private hands. The archive thus being built up will be of very great value to students who cannot see the material itself. It also serves as insurance against loss of the originals through dispersal of private collections or, in the case of museums, through destruction by earthquake, an ever present danger in the Central American republics. This year Sr. Tejeda has been working on Mr. Smith's Alta Verapaz pottery; on pieces in the Dieseldorff Collection, now the property of the National Museum; and on vessels recovered by Mr. S. H. Boggs in El Salvador.

Sr. Tejeda's younger brother, César, first employed in 1942 as assistant to Mr. Shook at Kaminaljuyú, developed great ability in mending and restoring pottery. During his work as preparator and in the field with Mr. Shook and Mr. A. L. Smith, he showed outstanding promise as an archaeologist. When this was brought to the attention of the authorities, he was granted a government fellowship for attendance at the Escuela Nacional de Antropología in Mexico City, where he has now matriculated. A fellowship was also given to Sr. Juan de Dios Rosales, for several years assistant to the late Dr. Manuel Andrade and to Drs. Redfield and Tax in their respective linguistic and ethnological investigations and, more recently, to Sr. Goubaud in the food survey. Such field experience as the Division has been able to give Srs. Tejeda and Rosales and such aid in acquiring academic training as it has been able to procure for them and for Srs. Alfonso Villa and Antonio Goubaud, largely through the generous and ready cooperation of the Rockefeller Foundation, is believed to be a most valuable contribution to the development of anthropology in Latin America, for although North American students can accomplish a certain amount of useful research, the major work must eventually be done by natives of the countries themselves, as it now is in Mexico by the able group headed by Dr. Alfonso Caso.

During the past winter Mr. A. L. Smith and Sr. César Tejeda made a survey of sites in the northwestern Guatemala highlands that are thought to date from late prehistoric times. Srs. Goubaud and Rosales, in the early months of 1945, completed the collection of data regarding food habits and food consumption of the Guatemala Indians and Ladinos. Dr. Kirk Bryan, professor of geology at Harvard University, spent two weeks in Guatemala studying physiographic conditions bearing upon the antiquity of human occupancy of that country. Reports on these investigations and on the ethnological work are appended. The Chairman

was in Guatemala during January and February for consultation with government authorities as to future undertakings. He also had opportunity to work in the Division office on archaeological collections made in former years. Temporarily unsettled political conditions prevented his visiting Mr. S. H. Boggs' excavations at Tazumal in eastern El Salvador, which are being carried on by the Salvadoran government, and for which Carnegie Institution has provided modest financial aid for the prosecution of certain stratigraphic studies. The Chairman later went to Boulder, Colorado, to confer with Drs. E. H. Morris and Anna O. Shepard regarding their work on Southwestern archaeology and ceramic technology; and to Albuquerque, New Mexico, to confer with Dr. F. V. Scholes. In California, he studied collections at Los Angeles and Berkeley.

At Cambridge, Mr. J.E.S. Thompson has begun the preparation of a comprehensive monograph on the Maya hieroglyphic writing. A report on certain aspects of this study appears below. Mr. Thompson has been awarded the Rivers Memorial Medal by Cambridge University for his contributions to Maya research. Miss Tatiana Proskouriakoff has begun a detailed analysis of dated Maya sculptures. This will not only lay a foundation for studies of other aspects of Maya art, but provide more reliable stylistic criteria than have hitherto been available for the dating of the many monuments which bear either no dates or illegible ones. Mrs. W. H. Harrison, in addition to her manifold duties as editor of the Division, has been compiling a dictionary of terms applicable to Middle American archaeology. This should serve to standardize usage and clarify nomenclature. The report on Kaminaljuyú by the Chairman, Dr. J. D. Jennings, and Mr. Shook has been finished and is now in press. In the field of Maya history, Dr. Scholes and Mr. R. L. Roys have continued the writing of their report on the Acalán-Tixchel area. Dr. Scholes and Miss Eleanor B. Adams, who now make their headquarters at Albuquerque, have been provided with quarters and given every facility for the prosecution of their work by the University of New Mexico.

1.35.

ALFRED V. KIDDER

Division of Historical Research

YB 45:195-199, 1946

With the return of all but one of the members of the staff who were in the armed forces or other government service during the war, it has been possible to resume normal research activities. "Reconversion" could not be rapid, however, for in each instance work had been abruptly interrupted and the individuals concerned were intensely preoccupied for years with matters so far removed from their former interests that there has of necessity been a period of reorientation and review, both of their own materials and of data that accrued during their absence. Furthermore, the almost entire halting of field investigations and, in the case of those in service, the impossibility of completing reports have thrown the Division program badly off schedule.

As has been stated in previous *Year Books*, it was planned that by the late 1940s all projects should be brought to a stage at which results could be summarized, conclusions drawn, problems formulated, and recommendations for future research be presented to the President and Trustees. This will still be done, but, as certain undertakings will have to be curtailed and others abandoned, it has become evident that immediate plans and long-range objectives must be restudied. For this reason, and also because the war hiatus and changing conditions in the postwar world make such a review singularly opportune, the members of the archaeological staff will hold a conference in Cambridge in September.

One of the most important matters for consideration at the conference will be that of recommendations to be made to the Institution. Regarding the nature and the locus of archaeological activity after the current series of investigations has been completed. Until now the major effort of the Division has been confined to the area occupied by Maya-speaking peoples, the archaeological work being keyed with studies of linguistics, ethnology, documentary history, and environmental conditions, in an attempt to follow the career of the Maya from the earliest times to the present. It has become evident, however, that hereafter it will be necessary to confine attention to the prehistoric period. This alters the situation to the extent that, if it seems desirable, the field of work can be broadened.

The problem of whether or not it will be best to continue intensive research on the preconquest Maya is a difficult one. The Maya were artistically and

intellectually the foremost group of pre-Columbian Americans. Knowledge of the origin, spread, and decline of their remarkable culture—knowledge which, it might be hoped, would bring understanding of what caused its efflorescence and what led to its ultimate withering, would constitute a very great contribution to the biology, so to speak, of civilization itself. Carnegie Institution has specialized on the Maya for over 30 years: most of the members of its archaeological staff are authorities on one aspect or another of Maya research; the Institution's work has reached a point at which each new bit of information is of cumulative value. On the other hand, what the Institution and others have done has made clear that the Maya were not, as was once supposed, uniquely outstanding as leaders in development of higher aboriginal culture. It is true that they were in many ways its most brilliant exponents, but it is not realized that, like the Greeks, they built on foundations reared by earlier peoples and that they were but one of many groups in both North and South America all of which played parts of greater or less importance on the New World stage. Yet our knowledge of this great human drama is very uneven. As to what took place in certain areas of southwestern United States, the Valley of Mexico, parts of the Andean region, we have a great deal of information; as to others, possibly, no less important and without question of much significance in the total picture, we know next to nothing. It might therefore be argued that the Institution should set itself the task of filling some of the most obvious gaps.

Decision on this fundamental question involves consideration of the interests and the special abilities of various staff members, of facilities for work in other areas, and of the plans of other private and governmental agencies. No matter how it is resolved, certain investigations now in progress; should, of course, be brought to the already mentioned stage of summary and interim report. On some of these, considerable progress was made during the past season. One or two are here briefly described; fuller statements regarding these and others appear in the body of this report.

A. L. Smith carried forward the reconnaissance survey of ruins in the Guatemala highlands. This project, inaugurated in 1945, is designed as a preliminary "stocktaking" of ancient sites in a hitherto very little known area which was heavily occupied over a long period in prehistoric times and which lies athwart one of the principal north-south routes of aboriginal migration and trade. It also occupied a position between the fertile and formerly even more densely inhabited Pacific slope and the valleys leading downward to the lowlands of Petén, where Maya culture achieved its highest development. Particular attention

is being paid to the chronological relations of fortified hilltop and undefended valley sites. It is hoped eventually to excavate intensively at one of each type. In the period under review, work was confined to the Department of Quiché, most of the four months available having been spent in the Néabaj area.

At Néabaj was made one of those unforeseen discoveries which so often upset the advance plans for archaeological fieldwork. Mr. Smith aimed to locate ruins over an extensive area and to obtain descriptions and photographs of them. Excavation was to be limited to few pits for the recovery of potsherd samples. He expected, this year, to cover northern Quiché and perhaps the whole of Baja Verapaz. All went according to schedule until he reached Néabaj. There, at a large site, he found a funnel-shaped depression in the frontal platform of one of the principal mounds. Guessing correctly that this must have been caused by the collapse of a vaulted tomb, and believing that it must lie close below, he obtained permission from the landowner, engaged diggers, and started hopefully down. To make a very long story short, the tomb proved to be no less than 30 feet down. To reach its floor, clear and remove its rich contents, and pack for hauling over mountain roads to the laboratory in Guatemala City the scores of specimens recovered, required a full month, by the end of which the rains had begun and further exploration became impossible. But the dislocation of the timetable was amply justified, for the tomb yielded some 45 specimens of pottery representing a very little known period, and one of the most beautiful collections of jade ornaments that has yet come to light.

Mr. Ruppert spent two months in Yucatán on what might be called a "cleanup" job, made necessary by certain gaps in the Division's published record of its many years' work at Chichén Itzá. The principal undertakings at that great site, such as the excavation and repair of the Temple of the Warriors, the Caracol, the Mercado, and the Temple of the Wall Panels, have been reported upon; a manuscript on the Monjas awaits the press. But a number of smaller buildings that were wholly or partly excavated have not yet been described. There are still others, unexcavated but in sufficiently good preservation to yield valuable architectural information. On return from his overseas duty in the American Field Service, Mr. Ruppert devoted himself to checking the notes taken by himself and others on the cleared but unpublished structures, and his own notes on structures at which no digging had been done. As is always the case, he found that more data and additional photographs were needed to enable him to prepare an adequate report. During the past winter these materials were gathered and the nature of several hitherto unidentified ruins was determined.

Gustav Strömsvik, having received his discharge from the Norwegian Navy, resumed his work at Copán. The decade of his activities there has worked wonders in the development of that in many ways most remarkable of all Maya ruins. Its extraordinary monuments have been re-erected, several of the most important buildings repaired, the great hieroglyphic stairway restored to its full height. The Copán River, which was steadily eating its way into the massive acropolis, has been diverted into a new channel. Yet by the wise sparing of many of the noble trees from the tropical forest that once engulfed Copán, by leaving untouched large portions of the wrecked and tumbled masonry of its temples, and by skillful restraint in the repair of those that he excavated, Mr. Strömsvik has made evident the high achievements of the ancient architects and sculptors without destroying the powerful psychological effect of what time and the jungle have wrought. Copán symbolizes both the glory of the Maya and the completeness of their fall.

During the year, Sr. Jesus Núñez, curator of the museum that houses the specimens recovered in the excavations, has acted as guardian of the ruins. The government of Honduras will see to their preservation in their present state.

Mr. Strömsvik opened the past season by repairing two of the monuments at Quiriguá that had been damaged by an earthquake. At Copán he put finishing touches on his work of former years. He plans to maintain headquarters there, and to do reconnaissance in the valleys to the east in order to determine the extent to which Maya culture penetrated in that direction and to study its relations to those with which it came into contact.

Dr. John M. Longyear, of the Peabody Museum of Harvard, who before the war had worked for the Division on the pottery of Copán, returned for six weeks to gather further data from a series of stratigraphic trenches. By courtesy of the Honduran government, which has cooperated most effectively with Carnegie Institution since the beginning of the project, Dr. Longyear was able to bring a large and valuable series of potsherds to Cambridge for laboratory study. An interesting and probably very important byproduct of his work was the finding in the river bank of a deposit of charcoal and flint and obsidian chips below a layer of sterile alluvium that underlies the deepest pottery bearing stratum. As not a single potsherd came to light, it is possible that this may represent a pre-ceramic culture, a thing not hitherto discovered in Central America. Further investigation is called for.

In addition to the field work above noted, several other projects were pursued. Dr. H.E.D. Pollock resumed his study of the great mass of material gathered before the war on the architecture of northern Yucatán.

Dr. S. G. Morley and Mr. J.E.S. Thompson continued their research on the Maya hieroglyphs; Miss Tatiana Proskouriakoff, hers on Maya sculpture, with special reference to determination of artistic criteria for the dating of monuments which bear no inscription or whose inscriptions are illegible. Miss Anna O. Shepard has sent to press a monograph on Plumbate pottery, a ware widely disseminated throughout Mesoamerica and therefore of much significance for working out the chronological and trade relations of cultures during the period of its manufacture. She has also been occupied with a classification of pottery vessel forms and with a study of symmetry in pottery decoration.

Robert E. Smith, in charge of the Division's Guatemala office, has devoted a large share of his time to cooperating with representatives of the Guatemala government in the organization of the National Institute of Archaeology and History, a body designed to further studies of the republic's rich pre-Columbian and postconquest past, and to administer its native and colonial antiquities. He has also served as Executive Chairman of the committee on the splendid new museum now being readied to contain the state's priceless archaeological collections, many of which are the product of the Division's excavations at Uaxactún, Kaminaljuyú, and other sites in Guatemala. Sr. Antonio Tejada, a member of the Division staff and likewise of the committee, has prepared dioramas, based on drawings by Miss Proskouriakoff, of a series of outstanding Maya ruins.

Mrs. W. H. Harrison, in addition to her duties as Division editor, has been engaged in compiling a dictionary of archaeological terms. Because of conflicting usages, personal predilections for certain terms, and, in many cases, necessity for further research, this greatly needed standardization of nomenclature is proving a long and difficult task.

The Division Chairman spent the winter in Guatemala working on the pottery of Kaminaljuyú and other highland sites. He visited A. L. Smith's excavations at Nébaj, those of Mr. Strömsvik at Copán, and those of the United Fruit Company at Zaculeu under direction of Messrs. John M. Dimick and Stanley H. Boggs. The Chairman is serving as adviser on the latter project, designed by the Fruit Company to provide for Guatemala an excavated and as far as possible restored ruin which will be more accessible to the people of the country and to tourists than are the lowland sites. Zaculeu, capital of Mam Maya at the time of the conquest, is singularly well fitted for this purpose. Many of its buildings are in a good state of preservation; it is magnificently situated at the foot of the towering Cuchumatanes range, close to the city of Huehuetenango, and easily reached, by motor or airplane from other parts of the country. The only archaeo-

logical activity outside the Maya field has been that of Dr. E. H. Morris, who has continued his study of the early cultures of southwestern United States.

Researches in documentary history and ethnology also have gone forward. Dr. Scholes and Mr. Roys have sent to press their monograph on Acalán-Tixchel. Dr. Chamberlain, who during the war was Senior Cultural Attaché at the United States Embassy in Guatemala, has resumed the writing of histories of Montejo's conquests of Yucatán and Honduras. Dr. Robert Redfield, Dean of the Social Sciences at the University of Chicago, has been prevented by other duties from active participation in the ethnological work of the Division, but he has kept in close touch with that of Dr. Tax and Sr. Villa. Reports on the investigations by the latter two on the modern Maya of the Guatemala highlands and of eastern Chiapas respectively are approaching completion. Sr. Rosales' study of the town of San Pedro on Lake Atitlán, and that of Lic. Antonio Goubaud on food consumption and food habits of the Guatemala Indians and ladinos, will be published in Spanish by the Guatemala government. Lic. Goubaud has been made Director of the Instituto Indígenista Nacional, an agency set up by the new and very progressive government of Guatemala for research on the social and economic problems of the Indians who form so large a percentage of the republic's population.

I.36.

ALFRED V. KIDDER

Division of Historical Research

YB 46:173-177, 1947

Success in archaeology, as in war, depends to a large extent upon an effective intelligence service and readiness to seize upon and exploit the "breaks." This is strikingly illustrated by the events of the past season's field work, during which information given by friends of the Division and at once followed up led to two of the year's three most rewarding undertakings.

First among these, perhaps indeed the single most important discovery ever made in the Maya field, resulted from word sent in by Mr. Giles G. Healey, who has long been interested in the Division's activities. In the winter of 1946 Mr. Healey penetrated the rough and practically unexplored jungle west of the Río Usumacinta in Chiapas, Mexico, to photograph the

primitive Lacandon Maya for a documentary film on Maya antiquities and the present-day Indians, which he is making for the United Fruit Company. Having with difficulty gained the confidence of the Lacandon, who are suspicious of all whites and are particularly loath to have them see the ancient temples at which they still conduct ceremonies, he was led by them to a small group of ruins three days' journey from the river. On entering one of the buildings, he was astonished to see that its three vaulted rooms were covered from floor to capstones with brilliant mural paintings.

Mr. Healey notified the Division of his find as soon as he was out of the bush, and at our request returned in July, accompanied by the Division artist, Sr. Antonio Tejeda. On the latter's report that the paintings far surpassed anything hitherto known, a party fully staffed and equipped to make copies and photographs, financed by the United Fruit Company, and led by Mr. Karl Ruppert, spent six weeks at Bonampak (Maya for "Painted Walls"), as the site has been named by Dr. Morley.

The murals depict processions, ceremonies, warfare. The human figures, nearly life-size, are executed with extraordinary naturalism. Costumes, ornaments, weapons, and musical instruments are reproduced with remarkable fidelity and in great detail. There are long hieroglyphic texts. The walls of this forgotten little temple have yielded fuller data on many aspects of Maya civilization at the height of the Classic period than one had dared hope would ever be recovered. Mr. Ruppert's account of the expedition, with description of the paintings and of the very fine sculptures that also came to light at Bonampak, appears in the body of this report.

The second important find of the season can be traced back to the eruption of the volcano of Santa Maria in 1902, which covered the neighboring slopes from the highlands to the Pacific coastal plain with a meter of white ash. The region is one of the principal coffee-producing areas in Guatemala, but to set out the coffee trees it is necessary to dig through the ash and well down into the underlying soil. Sr. Vitalino Robles, of Quezaltenango, owns a plantation there, the Finca El Paraiso, which is indeed a veritable archaeologist's paradise. Several years ago, in the course of planting, his workmen uncovered a series of stone slabs. Sr. Robles, an ardent amateur archaeologist, had the area cleared of ash, and digging under the slabs, came upon a large cache of pottery. Always a most helpful co-operator with the Division, he halted work and sent word to our office in Guatemala City. Sr. César Tejeda went to El Paraiso and assisted in removing the vessels, many of which were of Plumbate pottery. This ware is of much archaeological significance because it was very widely disseminated in trade

throughout Mesoamerica. It has been the subject of intensive study by Miss Anna O. Shepard (1948). The El Paraiso Plumbate proved to be of a type not previously known. For this reason it was desirable to obtain more material; in February Mr. E. M. Shook and the Chairman, at Sr. Robles' invitation, carried on further excavations.

The digging revealed the fact that the pottery cache had been made in a large, low mound, its contours masked by the heavy layer of volcanic ash. On widening and deepening the original Robles pit, we encountered, a rectangular tomb, its closely fitted wall and floor slabs painted red. It held two skeletons accompanied by much Plumbate pottery and jade. In another part of the mound were burials in great pottery urns.

While work at the mound was in progress, Mr. Shook investigated another outcropping of stone slabs at a spring in a nearby ravine. These turned out to be the outer edge of an extensive pavement which, sloping upward, ended at a narrow masonry-walled, slab-roofed passage that led into the side of the ravine. It was at first believed that this must be the entrance to a tomb, but when it was followed to its end it proved to open into a round chamber, 8 m in diameter, with two encircling benches and a central pit full of ashes and burned stones, evidently a communal sweat bath. It is of an entirely new type and was probably of ceremonial significance, for in clearing the frontal pavement we found enormous quantities of fragments of fine Plumbate vessels doubtless ritually broken.

Also adding significantly to knowledge of Maya archaeology were several very important tombs opened by Mr. A. L. Smith in the Department of Quiché, Guatemala, where in 1946 he had excavated a tomb of the Early Classic period in one of a group of mounds in the outskirts of the highland Indian village of Néabaj. Facing that mound was another. Surmising that this might contain other interments, he returned to Néabaj in 1947 and became involved in a most difficult but most highly productive piece of excavation. The mound's frontal platform proved to hold a series of tombs, altars, and ceremonial caches so stratified that their age, relative to one another, could surely be determined. The pottery vessels, incense burners, alabaster and marble vases, pyrite mirrors, gold and copper ornaments, and magnificent carved jades recovered illustrate the development of local arts over a period of some seven centuries; they prove that Néabaj was long the seat of an unexpectedly rich and flourishing community; and they indicate that a lively trade was maintained with the great centers on the Río Usumacinta. Mr. Smith's report appears below.

The foregoing were the highlights of a most successful season, which included, various other field activities.

A. L. Smith, before going to Néabaj, continued his survey of the northern highlands, mapping, noting, and photographing ruins in the Department of Baja Verapaz. Later he visited a number of sites in the Néabaj-Aguacatán-Sacapulas area in the company of Miss Tatiana Proskouriakoff, who gathered material for reconstruction drawings of sites and buildings of the sort contained in her *Album of Maya Architecture* (Proskouriakoff 1946). At Néabaj, Miss Proskouriakoff undertook the essential and in this case particularly difficult task of recording, on plans and sections, the exact location of tombs, caches, and architectural features as they came to light in the excavation of the mound.

E. M. Shook inaugurated a southward-heading survey of archaeological sites on the Pacific slope and coastal plain. He commenced operations in January, excavating at mound groups near Ayutla, on the Mexican border. At the same time Dr. Philip Drucker, of the Smithsonian Institution, began a similar survey on the Mexican side and worked northward. Dr. Drucker and Mr. Shook are keeping in close touch with each other and their combined efforts will open up a region hitherto almost completely neglected and one which not only was densely populated in ancient times, but was certainly always a highway for migration and commerce. Very interesting finds are to be expected.

Shook's investigation at Ayutla was interrupted by the opportunity to dig at Finca El Paraiso, which is also in the zone of his projected survey; and just as that excavation was finished, the United Fruit Company sent word of discoveries at Tiquisate, still farther south on the coastal plain, which had been made in breaking new land for banana farms. Given every facility by the Company, Shook spent several weeks at Tiquisate putting in test trenches and studying material that had come to light during the developmental operations.

The Chairman, as stated, worked with Shook at El Paraiso. He visited A. L. Smith's diggings at Néabaj and made several trips to Huehuetenango, in western Guatemala, where the United Fruit Company is carrying on an extensive project of excavation and repair at the ruins of Zaculeu, the ancient capital of the Mam Maya. Close touch is being kept with this work, which is yielding much information that bears on architectural and ceramic problems of interest to the Division. The technical aspects of the project are being handled by Messrs. S. H. Boggs and A. S. Trik, both former members of the Division staff; this year Mr. Gustav Strömsvik of the present staff was given leave to supervise the restoration of the Zaculeu ballcourt.

Another archaeological undertaking that keys well with the Division's program is an examination by Dr. Robert Wauchope, also formerly with the Division, of

Guatemalan sites occupied at the time of the Spanish conquest. The work is being done by the Middle American Research Institute of Tulane University.

An interesting and important development has been the establishment in Guatemala City of a very fine new anthropological museum. Mr. R. E. Smith, the Division's local representative, has been acting as chairman of the government's committee on planning and installation. This has occupied a large share of his time during the year, an activity justified by the fact that the museum will house the Division's great collections from Uaxactún, Kaminaljuyú, Nébaj, and other sites, as well as by the fact that the ample storage space now become available will permit transference from our office to the museum of the large and extremely valuable lots of potsherds gathered by us from all parts of Guatemala. In order to have more ready access to these materials, the office of the Division has been moved from downtown Guatemala to a building close to the museum.

The Division office has continued to serve as headquarters in Guatemala City for scientific workers from other institutions. This year it has been so used by Dr. L. C. Stuart, of the University of Michigan, who is making a herpetological survey of the Republic; by Dr. Wauchope, of Tulane University; and by Dr. T. Dale Stewart, physical anthropologist, of the United States National Museum. Dr. Stewart's work, under a grant from the Department of State, has been of great value to us. In past years, abundant data have been gathered on the bodily make-up of the Yucatecan Maya, but no comparable information has been available regarding the various Maya speaking groups of the highlands. Dr. Stewart measured, photographed, and blood-tested series of men and women at Sololá and Patzún. He also studied the considerable amount of skeletal material accumulated by the Division in past years, as well as that found during the Zaculeu excavations. He was supplied with a Division car and greatly aided by native interpreters put at his disposal by Professor Antonio Goubaud, Director of the Instituto Indigenista Nacional. Professor Goubaud's assistance furnishes a further example of the hearty co-operation the Division has always received from the governments of Guatemala and Mexico, the latter having granted duty-free entry of the equipment and supplies necessary for the Bonampak expedition and having delegated a staff artist of the Instituto de Antropología e Historia, Sr. A. Villagra, to accompany the party and work with Sr. Tejeda. For these and many other favors throughout the years, the Division is under deep obligation to Dr. Alfonso Caso, former Director of the Instituto; to Arq. Ignacio Marquina, its present head; and to Dr. Eduardo Noguera, Director of the Instituto's Department of Pre-Hispanic Monuments.

In the field of Maya linguistics, Dr. Norman McQuown, by arrangement with the Department of Anthropology of the University of Chicago, is giving half his time to study of the great mass of material gathered by the late Dr. Manuel J. Andrade. In December 1946 he made a trip to the Huastec Indians, a tribe in the Mexican state of Veracruz, who, although speaking a Maya language, are now, and apparently long have been, culturally quite distinct from the main southern group of the Maya.

Desk activities of the Division staff have also gone forward. Dr. S. G. Morley been engaged in preparation of guidebooks to Chichén Itzá and Uxmal, and has made further progress on a dictionary of Maya hieroglyphs. His large and fully illustrated book, *The Ancient Maya*, was published during the year (1946) in English by the Stanford University Press and in Spanish by the Fondo de Cultura Económica in Mexico. Its wide sale, calling at once for a second printing, indicates how satisfactorily it fills the long-felt need for a work on the Maya suitable for the general reader. Dr. H.E.D. Pollock continued working up the great amount of data on the architecture of the Puuc area in Yucatán gathered by him and Mr. Shook in the years before the war; Mr. Karl Ruppert, before leaving for Bonampak, was occupied with architectural materials collected last year at Chichén Itzá. Miss Tatiana Proskouriakoff devoted herself to the intensive study of Maya sculptural art; Mr. J.E.S. Thompson, to that of Maya hieroglyphic writing. Under part-time arrangements, with the Peabody Museum of Harvard University and the United Fruit Company's Zaculeu Project, Dr. J. M. Longyear worked on the pottery he obtained at Copán in the winter of 1946; Mr. Stanley H. Boggs, on that from his excavations for the government of Salvador at Tazumal. Mr. E. H. Morris continued preparation of reports on finds of former years made in Arizona caves occupied by early Southwestern agricultural peoples. Miss Anna O. Shepard completed a monograph on Plumbate pottery and a paper on symmetry in ceramic decoration, both of which are now in press.

Mr. R. L. Roys continued his research on Maya-language documents of the early colonial period. Dr. F. V. Scholes' work on Yucatán in the sixteenth century goes forward, with the assistance of Miss Eleanor B. Adams, at the University of New Mexico, where he is now Dean of the Graduate School. Dr. Robert S. Chamberlain has completed monographs on the conquest of Yucatán and of Honduras. He has accepted a post as Associate Professor of History at the University of Miami. Dr. Sol Tax, of the University of Chicago, has given half time to preparation of reports on the Quiché and Cakchiquel Indians of Guatemala; Sr. Alfonso Villa R., full time to data gathered in former years on the Maya-speaking tribes of Chiapas. The completion of

the foregoing historical and ethnological researches will bring to a close the activities of the Division in these fields. Under the respective direction of Dr. Scholes and Dr. Redfield, they have done much to throw light upon the findings of the archaeologists and to render understandable the conditions existing today in Mexico and Guatemala.

As of June 1, 1947, Miss Eleanor W. Ritchie resigned to be married, thus terminating her long, faithful, and effective service as Division secretary.

L37.

ALFRED V. KIDDER

Division of Historical Research

YB 47: 207–211, 1948

The work of the Division during the past year has to a considerable extent had direct bearing on aspects of Middle American research yet to be performed. Consequently, although the progress and results of current investigations are customarily the subject matter of the *Year Book*, something should be said in this report concerning plans for the future as they have taken shape during the two years since *Year Book* 45 set out the desirability of review and analysis. Interruption of the normal activities of the Division by the war, conclusion of certain non-archaeological elements of the Maya program, as well as approaching retirements made it opportune to assess past efforts, restudy the aims and methods of research, and consider most effective orientation for the Division's future effort in that field. General staff conferences consolidated divisional thinking, which benefited greatly also from informal discussion with representatives of other institutions engaged in studies of the Maya and related pre-Columbian civilizations.

For many years the Division has concerned itself with Maya history from the earliest times and over the entire area occupied by Maya-speaking peoples. Much attention has also been given to the conquest and colonial periods, to the life and customs of the present-day Maya, and to environmental conditions in the Maya country, studies designed to aid in the interpretation of the archaeological findings.

The review of what has been done to date in archaeology and allied fields has indicated that although many interesting problems remain unsolved and many

regions are still inadequately explored, a general outline of the Maya's career has been obtained. It was also indicated that indefinite continuance along the lines formerly pursued might lead to over-concentration on detail and narrowing of outlook. There seemed to be danger that, in attempting to go farther with a program covering so long a span of time and so large an area, the interests of individual workers might become so channeled and specialized that the manifest advantages of team work might be lost. For these reasons and also because of the greatly increased cost of field work, it appeared that there should be a quantitative reduction in objectives and a shift from a general study of the Maya past to an attack upon some specific phase thereof. This, it was thought, should be a period already shown to be particularly significant; one on which the attention of the entire staff could profitably be focused; and one promising to yield, within a predictable time, results of both historical and methodological importance. These considerations led to the recommendation, for inauguration in 1951, of an intensive study of the protohistoric period of northern Yucatán.

The four or five centuries preceding the Spanish conquest of Yucatán were times of stress and change. The great southern cities had been abandoned. Maya culture, however, had persisted in the north. But whereas the Maya of classic days had apparently been free to develop their remarkable civilization without foreign interference, their Yucatecan successors became increasingly affected by influences and by actual migrations from highland Mexico and the Gulf Coast. New artistic, and governmental ideas surely made themselves felt. But as these are as yet only imperfectly understood, we do not know to what degree they were instrumental in bringing about the political alliances, the inter-group rivalries, and, finally, the open conflicts which seem to have caused the general decadence of the sixteenth century.

For attack on this interesting and, from the point of view of historical theory, very important period we fortunately have large amount of information regarding preconquest times in the form of chronicles, some written by native scholars, some, at second hand, by Spaniards. The checking of these accounts is one of the most promising aspects of the proposed research. Certain students have taken them at face value; others are of the opinion that although the events recorded doubtless took place, their sequence may have been seriously garbled. The principal points at issue concern the times of founding, length, of occupancy, and dates of abandonment of various cities whose ruins are identifiable. As the problems have to do with relative chronology, they can, in most cases at least, be settled by excavations at the sites in question. It is most

desirable that this be done, not only to permit accurate reconstruction of what actually took place in Yucatán, but also in order that methods may be worked out for testing, by archaeological evidence, the reliability of these, and of similar traditional narratives bearing on the history of other New World civilizations in Mexico and the Andean region.

The activities of the past year were a start toward clearing the decks for the proposed new program. This entails completion of all current field investigations and the making of certain surveys needed to round out the former general study to determine the most favorable sites for intensive investigation. The major task of most staff members, however, has been, and for the next two years will continue to be, the writing and seeing through the press of final reports on all work accomplished under the old program.

The most important field operation of the past season was a second expedition to Bonampak, a Maya city of the Classic Period recently discovered in the densely jungled country west of the Usumacinta River in the Mexican state of Chiapas. As reported in the last *Year Book* [Chapter 19.1 this volume], one of the temples at Bonampak contains mural paintings, remarkable for elaborateness and skill of execution, for variety and interest of subject matter and for the splendid state of their preservation. The recording of these unique paintings has been a major undertaking of the Institute of Anthropology and History of the Mexican government and, Carnegie Institution, most generously financed by the United Fruit Company. In 1947 the murals of the first of the temple's three chambers were copied in water color and photographed with panchromatic and infrared film. The 1948 party consisted of Mr. Gustav Strömsvik, archaeologist, and Sr. Antonio Tejada F., artist, both of the Division's staff and Srs. Agustín Villagra and Hipólito Sánchez, artists of the Institute of Anthropology and History. Working long hours under most difficult and trying conditions the artists succeeded, before the onset of the rains made withdrawal from the bush necessary, in completing the copies of the murals in the second and third rooms. An account of the work and a description of the newly recorded paintings are contained in Mr. Strömsvik's and Sr. Tejada's reports below.

This second and final Bonampak expedition was the only major piece of field work that had been planned for the winter of 1948. But as so often happens in archaeology, an accidental discovery necessitated an entirely unforeseen, and in this case most profitable, excavation.

A building boom at present going on in Guatemala City has called for the manufacture of great quantities of adobes, tiles, and bricks. The best material for these is clay which has already been mixed, tempered,

and puddled, a requirement perfectly fulfilled by the fill of ancient earth mounds. As a result, a number of brickworks have been set up at the great archaeological site of Kaminaljuyú in the outskirts of the city, and many mounds are being destroyed. At the largest of all the Kaminaljuyú mounds, the workmen of a government brickworks cut into a tomb. When this was brought to the attention of the superintendent, the digging was stopped, the Division's Guatemala office was notified, and Mr. E. M. Shook made a preliminary examination. He found that the tomb lay in the center of the mound, about 13 m above ground level and about 7 m down from the summit. The chamber, filled with earth following the ancient collapse of its log roof, had been broken into on one side; the fragments of many vessels were scattered below. The pottery was of the Miraflores Phase, confirming an earlier suspicion that, in spite of its great size, the mound had been erected during that very early period.

As the only Miraflores tomb previously known had been opened by an amateur, and as the present one was obviously very rich, Mr. Shook dropped all other work and undertook its excavation, a long and difficult piece of work because of the necessity of removing a tremendous overburden and because of the masses of crushed vessels it was found to contain. Of these there were probably over 300 (an exact count awaits their restoration). There were also very beautiful small stone and jade containers, little stone mortars in the form of frogs, a large eccentric flint, and a so-called "mushroom stone." Neither of the latter types had been thought to have been produced at so early a date.

Important finds did not end with the tomb, for as the cutting by the government's workmen progressed, it was seen that the mound had grown by accretion and, that it contains well preserved remains of a sequence of several adobe structures, the tomb having been dug into the summit platform of the next to latest. It is quite possible that others will be found below, and certain that much valuable information as to Miraflores ceremonial architecture, about which we have hitherto known nothing, will be gained as the work progresses. We are greatly indebted to the officials of the Department of Public Works, who have co-operated to the fullest extent by supplying workmen at no expense to us and by sparing uncovered structures until they can be carefully cleared, studied, and recorded. Thus we shall have opportunity to gather data on a most instructive and perhaps unique architectural complex, and one whose excavation would have been far too costly for us to undertake. Mr. Shook's report on the mound appears below.

During the season, data have also accrued as to the representation at Kaminaljuyú and vicinity of the

Las Charcas and Sacatepéquez; phases, now proved to be even older than Miraflores. To date these are known only from their pottery and a single Sacatepéquez grave found by Mr. Shook in a road-cut west of Guatemala City. Ceramically, both are as highly developed as Miraflores. The more primitive phases which must have preceded them still elude discovery.

So much for field work. Most members of the staff have been engaged in laboratory and library studies, and in writing reports, activities necessary for bringing the old program to completion and preparing for the Yucatán project.

Dr. Pollock, who is carrying the principal load of the internal administration of the Division, has also continued work on his report on the architecture of the Puuc cities of Yucatán, which contain, some of the finest and best-preserved buildings ever erected by the Maya. They are believed by some students to have been products of a renaissance that took place after the abandonment of the Classic southern centers, and by others to date from the latter part of the Classic Period. Solution of this very important problem is one of the objectives of the proposed new program. During the winter, Dr. Pollock visited Yucatán to check certain earlier observations on the ruins and to examine sites which are under consideration for future study. His report appears below.

Mr. Karl Ruppert, who was in charge of the expedition to Bonampak in 1947, has written a report on the architecture of that site. Further observations on some of the buildings, made in 1948 by Mr. Strömsvik, have been incorporated. The greater part of Mr. Ruppert's time has been devoted to study of the notes on, and the photographs and plans of buildings excavated in past years at Chichén Itzá that have not been published. The resultant report will complete the record of the Division's work at Chichén Itzá and will form one of the bases for continued research on the architecture of northern Yucatán.

Mr. A. L. Smith has devoted the period under review to materials gathered during his survey of archaeological sites in the Guatemala highlands and in his excavation of the very rich tombs discovered by him at Nébaj. He has completed the final report on the Division's work at Uaxactún.

Mr. R. E. Smith, who makes his residence in Guatemala and is in charge of the Division office there, has given much time to the new Guatemala National Museum of Archaeology and Ethnology. As chairman of the National Institute of Anthropology and History's committee on the museum, he has been active in the planning of the museum and, with Dr. Paul H. Nesbitt, in the installation of its magnificent Maya collections. Dr. Nesbitt's invaluable services were, through the efforts of Mr. Smith, made available to the Rockefeller

Foundation. Mr. Smith's monograph on the pottery of Uaxactún is approaching completion.

Miss Tatiana Proskouriakoff has continued work on Maya sculptural art with special attention to the stelae of the Classic Period. The methods employed in her analytical study of these monuments were described in the last *Year Book*. It has the double aim of tracing the development of Maya stone carving, an art in which that people led all others in the pre-Columbian New World, and of determining objective criteria which will permit the dating of stelae and other sculptures that bear no inscriptions or inscriptions that have been so damaged as to resist decipherment. Miss Proskouriakoff has also made a series of restoration drawings, similar to those in her *Album of Maya Architecture*, of sites and buildings in the Guatemala highlands. The necessary architectural data were gathered by A. L. Smith; field sketches of the often very spectacular setting of the groups were made by Miss Proskouriakoff.

The late Dr. Sylvanus G. Morley spent the season from November 1947 to May 1948 in Yucatán carrying forward his epigraphic researches. Although Dr. Morley's death in Santa Fe on September 2, 1948, occurred after the close of the period covered by this report, there must here be voiced the deep personal grief of his colleagues of the Division, and their sense of the irreparable loss to Maya research in the passing of its most devoted and most eminent student. A statement regarding his great contribution to knowledge of the Maya will be prepared for the next *Year Book*.

Mr. Thompson has continued his studies of Maya hieroglyphic writing. The introductory volume to this work is virtually completed, and it is anticipated that the book will be ready for the publishers next year. Mr. Thompson also has given his time as editor of the Division's series of *Notes on Middle American Archaeology and Ethnology*.

The Chairman spent the winter in Guatemala working on the collections of potsherds made by A. L. Smith during his highland survey. He also made notes on, and photographed the pottery and artifacts from the Nébaj tombs for a joint paper with Mr. Smith. The Nébaj materials are of much interest, not only for the fine preservation of the pottery and the outstanding beauty of the jade carvings, but also because both pottery and jades, evidence active trade relations between Nébaj and Classic centers in the lowlands. The Chairman has continued to act as archaeological adviser to the United Fruit Company, which is engaged in the excavation and restoration of the important ruins of Zaculeu in western Guatemala.

In the field of history and native Maya literature, Mr. R. L. Roys spent a considerable part of the year in proofreading and indexing the monograph on the

Chontal Indians of Acalán-Tixchel by himself and Dr. F. V. Scholes, now in press. He also made an intensive study of Maya prophecies to investigate the meaning of various obscure phrases and mythological references. For this purpose he was obliged to make a further study of the Ritual of the Bacabs, a book of medical incantations. The results of his research may form an extensive appendix to Mr. J.E.S. Thompson's work on the Maya glyphs, as it is possible that certain of the stock phrases of the prophecies and incantations also formed parts of the hieroglyphic inscriptions and that cross-identification may throw light on the meaning of glyph groups not now decipherable. Mr. Roys has been made Honorary Research Professor of Anthropology at the University of Washington.

Dr. Scholes, now Dean of the Graduate School and Vice-President of the University of New Mexico, continues, for the Division, his research and writing on the history of Yucatán, assisted by Miss Eleanor B. Adams. In addition to work on the above-mentioned joint monograph with Mr. Roys on Acalán-Tixchel, he has been engaged in several studies preliminary to, and laying foundations for his *Yucatán in the Sixteenth Century*, which will form the fourth and final volume of a series on the early history of the peninsula, the first being Mr. Roys' *Indian Background of Colonial Yucatán*, already published; the second and third, Dr. Scholes' and Mr. Roys' *The Maya Chontal Indians of Acalán-Tixchel*, and Dr. Robert S. Chamberlain's *Conquest of Yucatán*, both in press.

L.38.

ALFRED V. KIDDER

Division of Historical Research

YB 48:215-219, 1949

In archaeology it is always difficult, often impossible, to adhere to a prearranged schedule of field work. The archaeologist never knows what lies underground: its quantity, the state of its preservation, or the often entirely unexpected leads and problems it may open up. Also, he must be prepared temporarily to abandon any given undertaking because of some reported discovery which, for one reason or another, must at once be exploited. This is particularly true of work in the Maya area, in which so little actual excavation has been done that one can seldom predict what or how much or

how little one is going to find; there is so great an amount of unexplored country that at any time may come word of a ruin of such obvious importance that it must immediately be given at least preliminary investigation.

The finding of the unique wall paintings at Bonampak, described in the last two *Year Book* reports, was a case in point. Another was the discovery, in 1948, of the extraordinarily rich tomb of the Miraflores Phase at Kaminaljuyú, in the outskirts of Guatemala City. The clearing of this tomb not only took the time of two staff members for many weeks and further required many months for the study of the specimens recovered, but also proved that native Middle American culture had reached so high a state of both technological and social advancement at what had formerly been believed to be a still formative period that future investigation of the origin of Middle American civilization will have to be rather radically reoriented.

The Division's troubles at Kaminaljuyú did not end with 1948. The upper benches of the tomb, which lay several meters down from the top of a 20 m mound, could not be entirely excavated during that year without burrowing too deeply for safety into a tremendous overburden of hardpacked earth. So, with labor kindly supplied by the Government of Guatemala, the off season was employed in cutting it away, with the result that a second tomb, set somewhat higher, came to light. The extremely difficult task of its excavation and the recovery of its many mortuary offerings was carried out by Mr. Shook.

To Mr. Shook also belongs the credit for identification of a hitherto unrecognized stage of culture older than Miraflores but younger than one we have called Las Charcas. The original find, a burial accompanied by much pottery, was made in the side of a road-cut west of Guatemala City in the Department of Sacatepéquez; this name has been assigned to the phase. Subsequently, excavation for the storage tank of a gasoline station near Chimaltenango yielded a further large Sacatepéquez collection.

Study of the enormous amount of Miraflores material from Kaminaljuyú, of the Sacatepéquez specimens, and of a rich new Las Charcas find has shown that these three phases were sequent stages in the (we believe very long) development of an important Preclassic highland culture that culminated in Miraflores. The forerunners of that culture, even in Las Charcas times far from primitive, are still unknown, and we cannot as yet explain the apparently abrupt and certainly very great change marked by the opening of the Classic Esperanza Phase at some time during the early centuries of the Christian era.

Establishment of the Las Charcas-Sacatepéquez-Miraflores sequence contributes significantly to knowledge of Guatemala highland prehistory. From the

broader view of the history of art and technology, its potential value is great, for it provides a large and fully documented body of data to supplement our, scanty knowledge concerning such aspects of cultural growth as developments in the techniques of pottery making and the life histories of decorative styles. Much of our theorizing on these matters has been highly speculative, because based on series of specimens whose relative ages are uncertain. The only weakness of the present sequence, and it is of course a very serious one, is due to our ignorance of the amount of time that elapsed between earliest Las Charcas and latest Miraflores. For all we now know, it may have been 200 or a thousand years. But there is hope that further perfection of methods for employment of radioactive elements for determination of the age of archaeological specimens may eventually permit reasonably accurate dating.

A second unplanned investigation was made necessary by road work at Asunción Mitá in eastern Guatemala, where in the elimination of a curve some large mounds were being cut down. In one of these, previous digging by pot hunters had exposed an earlier structure containing vaulted chambers. Mr. Strömsvik accordingly went to Asunción Mitá in April to make record of such parts of the building as had been exposed. Both architecture and pottery seem to indicate connections with Copán during the so-called Acropolis Period. During his visit, Mr. Strömsvik took opportunity to reconnoiter the region, mapping and collecting potsherds from a number of other sites.

The final season of Mr. A. L. Smith's survey of the Guatemala highlands was devoted to the Departments of Quiché, Alta Verapaz, and Chimaltenango. Mr. Smith revisited Néabaj, Quiché, where he made remarkable finds in 1946 and 1947. This year a tomb, located in 1947, was excavated. Among the mortuary offerings of pottery and jade was a vessel, apparently a trade piece from Alta Verapaz, which is believed to date from the early years of the Late Classic Period. If this is confirmed, will show that, part at least of what have considered the Early Classic period of Néabaj was contemporaneous with the beginning of the Late Classic of Petén; in other words, that we must recognize a certain amount of cultural lag in the highlands.

After a survey of the San Andrés Sajcabajá region of Quiché, where a number of large sites were mapped, Mr. A. L. Smith, accompanied by Mr. R. E. Smith and Dr. Stephen de Borhegyi, proceeded to Alta Verapaz. Sites in the neighborhood of Cobán and in the upper and middle drainage of the Río Polochic were examined. Some of these contain remarkably fine construction in which very large and accurately cut stone slabs were used. Potsherds were scarce, but those that were recovered and certain vessels from a tomb make it evi-

dent that the ruins in question date from the Late Classic Period.

Finally, A. L. Smith visited the ruins of Mixco Viejo in the drainage of the Río Grande. From this extensive site, known to have been occupied at the time of the Spanish conquest, he recovered a large collection of potsherds illustrating the hitherto little-known wares of the sixteenth century.

Mr. E. M. Shook, as already stated, excavated a second rich tomb in the great Miraflores phase mound at Kaminaljuyú. The specimens from the tomb, hundreds of thousands of potsherds from the fill of the mound, more thousands from various other mounds at Kaminaljuyú that are being cut down for brick making, and still others from road operations to the west, are being classified and studied by Mr. Shook and the Chairman.

The most important field operation of the period under review was the Campeche expedition of Dr. George W. Brainerd and Mr. Karl Ruppert. Past work of the Division had developed a sound framework of knowledge relative to much of the southern area of the Maya and to northern Yucatán. There existed, however, an intervening area that was but sketchily known and little understood, our lack of knowledge being particularly acute in respect to ceramics. Although this little-known area stretches across the peninsula from coast to coast, it seemed of particular importance to gain knowledge of the so-called Río Bec and Chenes areas of eastern Campeche. By making a survey of the pottery of these areas it was hoped that relationships might be established with the Petén region to the south and Yucatán to the north, and that the cultural development of Yucatán might thus be anchored more firmly to the relatively well dated cultures of the south. Such linking up of southern and northern areas seemed of particular importance, before embarking upon any new operations in Yucatán.

By arrangement with the University of California at Los Angeles and the Southwest Museum, Dr. Brainerd obtained leave from those institutions for a period of six months to carry on this work for the Division. He was assisted by Mr. Ruppert. During the winter and spring they conducted excavations at the Chenes sites of Santa Rosa Xtampak and Dzibilnucac, and at a number of Río Bec locations centering about the site of Xpuhil. At the time of writing this report we record that the materials collected are being analyzed; the study has progressed far enough, however, to indicate that the Chenes-Río Bec architectural styles and the associated pottery are in part contemporaneous with the Puuc remains in Yucatán and with the Late Classic (Tepeu) in the Petén. The Petén association should provide approximate dating, in terms of the Maya calendar, of Chenes-Río Bec and Puuc remains,

a dating that has at times been hotly debated. There is every reason to hope that the work of Brainerd and Ruppert has made an important advance toward solving the relative chronology of the northern, intermediate, and southern areas, and that the work also will throw light on cultural influences between areas.

Laboratory and desk work again occupied a large proportion of the efforts of the staff. Miss Shepard has continued her work in ceramic technology. A special project dealing with pottery of the southwestern United States and designed to acquaint archaeologists more generally with the applications and significance of ceramic technological data is nearing completion.

Miss Shepard has also given time to the preparation of a ceramic handbook for the use of archaeologists. Miss Proskouriakoff has brought to completion her initial studies of Maya sculpture. It is anticipated that this work will go to press by the end of this year. During the period under review Mr. Thompson completed and submitted the manuscript of the introductory volume of his studies of Maya hieroglyphic writing. This volume is now in press. Similarly completed and in press is Mr. A. L. Smith's work on the excavations at Uaxactún. Prior to entering the field with Dr. Brainerd, Mr. Ruppert continued his study, preparation, and arrangement of unpublished materials dealing with earlier activities of the Institution at Chichén Itzá. Dr. Morris made further progress toward the publication of his researches in Southwestern archaeology. Although by far the greater portion of his efforts was devoted to administrative duties, Dr. Pollock gave some time to his study of Yucatán architecture.

Dr. Norman A. McQuown, by arrangement with the Department of Anthropology of the University of Chicago, again gave part of his time to the Institution for researches in Maya linguistics. Dr. McQuown spent five months in Guatemala, working mainly on the Mam language, but giving some attention to other highland Maya languages, to Xinca, and to arranging for collaboration with a number of individuals in the field. Dr. McQuown's field trip marks the end of active participation by the Institution in the field of Maya linguistics. It is hoped, however, that the work will continue under the auspices of the Department of Anthropology of the University of Chicago.

Mr. Roys spent two months in Yucatán in continuance of his studies of native Maya literature and the history of the Maya area. As in the past, he devoted much of his time to field research bearing upon the political geography of the region at the time of the Spanish conquest. He also gave special attention to the search for conquest-period sites that might merit particular attention under the Division's proposed program of operations in Yucatán.

Most of the above-noted activities have been devoted to winding up the over-all study of the Maya and to clearing the deck for intensive research on the archaeology and history of northern Yucatán. In focusing its attention on this field, the Division is returning to the area in which, over 40 years ago, opened the long and fruitful career of Sylvanus Griswold Morley as a Mayanist.

With Morley's death on September 2, 1948, the Maya, ancient and modern, lost their most tireless and effective advocate. His whole adult life was dedicated to the furtherance of Maya research. That he was able to accomplish so much was due to a unique combination of scholarly ability, skill as a promoter, unbounded energy and limitless persistence. His firsthand contributions as explorer, recorder of texts, and student of the hieroglyphs were outstanding. His driving enthusiasm resulted in the entrance of Carnegie Institution into the Maya field. He lost no opportunity to induce agencies to cooperate or to undertake independent investigations. He was thus largely responsible for the fact that so many persons have been to devote themselves to Maya studies.

Morley early realized that in the last analysis any branch of research is made possible only by popular understanding of its aims and appreciation of its value. He was therefore tireless in publicizing the Maya by lectures and writings. With the same end in view, and also to preserve for the future the finest examples of Maya architecture and sculpture, he inaugurated at Chichén Itzá and continued at Quiriguá and Copán the custom of stabilizing and repairing excavated buildings and re-erecting fallen monuments. This has greatly helped to stimulate interest in their antiquities on the part of the governments of the countries in which these ruins situated, and has led to the preservation of much that might otherwise have been lost.

Morley's scientific, practical and promotional accomplishments were many. But, in the long run, undoubtedly the greatest was his success in inculcating confidence in the good faith of American scientific agencies and in bringing about the close and cordial relations, both personal and intellectual, that now exists between those scholars of the United States and of Latin America whose common interest is in the prehistoric past of the New World.

On June 11, 1949, the Chairman received the honorary degree of Doctor of Science from the University of Michigan.

1.39.

ALFRED V. KIDDER

Division of Historical Research

YB 49:191–194, 1950

During the period under review all members of the Division staff were engaged in preparing reports on work done on part of the inclusive program of Maya research that is being brought to conclusion at the end of the present calendar year. By that time there will have been published or made ready for the press, or be close to completion, papers covering all the Division's major archaeological investigations in the Maya field.

This has been a long and arduous undertaking. It is not generally realized, outside the profession, how great a disproportion exists between the time spent in excavation or survey and that required to digest the results, to make the relevant comparative studies of the literature and of museum collections, and finally to combine and present the information gained in such form as to be of maximum value to other students; to say nothing of the reading of proof. In the case of most archaeological enterprises, the ratio of desk to field work must be at least as 3 or 4 to 1; when finds are unusually numerous, or when particularly far-reaching problems are involved, it may be much greater.

Yet this task must always be carried through. The duty to record their findings fully and accurately rests more heavily on archaeologists than on workers in any other discipline. Should a biologist or a student of the physical sciences fail to report on his research, it is unfortunate; in most cases, however, only to the extent that effort and funds have been wasted. There will always be a continuing supply of the same raw data for the use of other observers. But materials for the study of man's past are not only limited, but also expendable. Excavation, even if structures and monuments can be preserved and if specimens are housed in a museum, inevitably leads to removal of graves, refuse deposits, and invaluable stratigraphic evidence as to the relative age of objects. Once cleared, a prehistoric site loses much, often all, meaning, and if the results obtained have not been adequately recorded, another page will have been ripped from the already time-mutilated volume of human history.

The members of the Division staff have been under special obligation in this respect because of the unique facilities they have enjoyed. Nearly all other archaeologists are employed either by universities or by museums; many of them hold positions in both. They carry heavy loads of teaching and curatorial duties. Time for field work is limited. Under the exist-

ing academic setup, in addition, anyone who attains distinction in his field is almost certain to be hampered by administrative assignments that have little or no bearing on his intellectual interests. We are freed from all the above burdens. Furthermore, it has been made possible for us to publish promptly.

Thanks to these exceptional opportunities, the Division has been able to accomplish a great deal of research and to produce a large number of reports thereon. The value of its work has lain, we believe, in the bringing to bear upon the problems of Maya history the resources and the viewpoints of many different disciplines. And, on the strictly archaeological side, the Division has applied to Maya sites, for the first time on any considerable scale, methods of stratigraphic excavation with intensive study of the specimens recovered. This "dirt" archaeology, largely the dissection of refuse middens has thrown light on the humbler aspects of ancient Maya life, has permitted the dating, relative to one another, of many of the more spectacular remains, and has thus rendered more meaningful, in terms of the evolution of Maya material and aesthetic culture, the temples and sculptures and hieroglyphic inscriptions to which the lion's share of attention had previously been given.

The program of Maya research inaugurated with the establishment of the Division in 1929 was a very ambitious one. It could not be carried through as originally planned in the hopeful days before the depression and the war. There is not space here to review its objective's, to summarize its results, or to consider the reasons for its successes and its failures. This will be done in a forthcoming report. But, to anticipate, it may be stated that attempt was made to cover too great a range of time and too extensive an area. The work envisaged for the immediate future, which will be restricted to the later prehistoric career of the Maya in northern Yucatán, will not suffer from these errors.

Active field work in preparation for the Yucatán program was begun in November 1949, with the mapping of the ruins of Mayapán by Mr. Morris R. Jones, of the U. S. Geological Survey, who was kindly given leave of absence by the Survey to undertake this long and difficult task. An accurate map of Mayapán was needed, as intensive study of that site will commence during the coming winter. Mayapán has been chosen for primary attention because of its great importance as a political center during the troublous centuries before the Spanish conquest. It was a member of the so-called League of Mayapán when its rulers gained ascendancy, heads of other groups were required to maintain residence there. It is frequently mentioned in the native chronicles and Spanish accounts based on native legend histories. It is hoped that its excavation

will yield information as to the later prehistoric cultures and also provide archaeological checks on the reliability of the chronicles. As Mr. Jones states in the report that appears below, the dense bush that covers the site conceals an extraordinarily great number of remains.

In Guatemala no new investigation initiated, but both Mr. Shook and the Chairman from time to time found it imperative temporarily to abandon their desks in the Guatemala office to record finds made at the nearby site of Kaminaljuyú and elsewhere in the course of road building and other public and commercial undertakings. At Kaminaljuyú, Mr. Shook salvaged materials that would otherwise have been destroyed, which add enormously to knowledge of the earliest highland culture now known. During the year he has been engaged in preparing reports on this and other early cultures and on his very prolific former excavations at later sites on the Pacific slope.

Mr. R. E. Smith continued the writing of his monograph on the pottery of Uaxactún, now approaching completion. In addition to this and his duties as the Division's representative in Guatemala and those connected with his effective chairmanship of the Guatemala National Museum's Committee on Archaeology, Mr. Smith found time for a short trip to the Department of El Petén to procure samples of the few wooden beams still remaining in the ruins of Uaxactún. These, it is hoped, may be dated by means of the newly developed carbon 14 method for determining the age of organic materials. Other specimens that can be used for this potentially most important type of research were recovered by Mr. Shook. These consist of charcoal and wood from several sequent early horizons at Kaminaljuyú. As their age, relative to one another, is known from their stratigraphic relations, they should provide, when dates in terms of years have been assigned to them by the above-mentioned method, a very valuable check on its reliability. Because of this, because of their archaeological importance, and also because it is unlikely that they can be duplicated, it has been decided not to submit any of these specimens for analysis until the laboratory techniques involved have been further perfected and tested.

Dr. Howel Williams, of the University of California, who was carrying on volcanological research in Central America during the past winter, spent some weeks at Managua, Nicaragua, studying the past eruptive conditions that led to an outflow of now consolidated mud in which footprints of men and animals were impressed. Dr. Williams' hopes of finding organic substances for Carbon 14 age determination in the deeply buried footprint stratum were disappointed. His examination of the sources and the nature of the various deposits overlying that stratum leads him to

believe that, although it is of considerable antiquity, it was probably laid down not more than 5,000 years ago.

During the year there was published the monograph of Mr. J.E.S. Thompson on Maya hieroglyphic writing; that of Miss Tatiana Proskouriakoff on the sculptured Maya monuments of the Classic period was completed and sent to press. They are comprehensive studies of intellectual and artistic activities in which the Maya surpassed all other peoples of the New World. Each serves to round out the more general study of the Maya on which the Division has so long been engaged, and each lays firm foundations for work on these important aspects of Maya culture during the later stages that will be under investigation by the Division in future years.

Mr. A. L. Smith's monograph on Uaxactún has been issued. It is a detailed account of the longest and most thorough excavation of a Classic Maya city that has yet been made. Like the above-mentioned works by Mr. Thompson and Miss Proskouriakoff, it is of value in completing the old program and provides a basis, in this case for studies of later architectural developments, for researches in northern Yucatán. Mr. Smith is now engaged on a final report on his archaeological survey of the Guatemala highlands. Another publication of much importance will be that of Mr. Karl Ruppert, on the several buildings, not previously reported upon, that were excavated during the Division's many years of activity at Chichén Itzá.

Dr. Anna O. Shepard has been preparing a book on ceramic technology for the use of archaeologists. It should perhaps be called a ceramic primer, because in spite of the fact that archaeologists constantly employ the evidence of pottery for determining changes in, and contacts between, cultures, they know far too little of the fundamentals of pottery making, of the nature of clays and tempering materials, and of the behavior of clays under varying methods of firing. Dr. Shepard has also been applying the methods of ceramic technology to a problem that has arisen in regard to the relationship of two important prehistoric cultures of the southwestern United States. Her interim report, which appears below, shows how greatly laboratory techniques can contribute to solution of such problems.

Mr. Gustav Strömsvik has closed the headquarters that the Division has maintained since 1936 at the ruins of Copán, Honduras, and has been engaged in writing reports on structures excavated at that site. Dr. J. M. Longyear, now of Colgate University, has completed a monograph on the pottery of Copán.

The Chairman, thanks to Dr. Pollock's having assumed all administrative duties, has been able to make progress on joint reports with A. L. Smith on excava-

tions at Nébaj, in the Guatemala highlands, and with E. M. Shook on those of the rich Preclassic tombs discovered in 1947 and 1948 at Kaminaljuyú, in the outskirts of Guatemala City.

During the year Mr. Raymond H. Thompson has been appointed a Carnegie Institution Fellow for Ceramic Studies, and Mr. Robert H. Barlow a part-time Fellow for research on the Documentary History of the Maya.

The meeting of the 29th International Congress of Americanists in New York in September 1949 led a large number of the Division staff to take advantage of its accessibility. The Chairman of the Division served as Secretary of the Committee on Organization and later as Secretary General of the Congress. Papers were presented by Proskouriakoff, "Non-Classic traits of Maya sculpture in Yucatán," by Shook, "Present status of knowledge on the Preclassic horizons in Guatemala," and by J.E.S. Thompson, "Some pluvial symbols and glyphic elements common to Teotihuacán and the classical Maya." In May 1950 Mr. Shook lectured at the Guatemalan-American Institute, Guatemala City, on the "Development of Maya architecture."

I.40.

H.E.D. POLLOCK

Department of Archaeology

YB 50:221–229, 1951

The period covered by this report was a notable one in the affairs of the Department. It marked the completion of a program of investigations that had been under way for over 20 years, and saw the official beginning of new researches with different orientation, with new aims and objectives. On November 1, 1950, A. V. Kidder retired as Chairman of the Division of Historical Research. On January 1, 1951, by action of the Trustees of the Institution, the Division of Historical Research became the Department of Archaeology, a designation more accurately describing our area of operation.

Changes of this magnitude obviously were not accomplished without much planning. As long as five years ago staff discussions were initiated in anticipation of the course that our work should follow on completion of the then current program. From time to time the results of such discussions were gathered together in the form of memoranda for the use of the

President and the Trustees. Some of the planning and thought on this subject has been referred to in previous annual reports, notably in *Year Book* 47, where the future work of the Department and some of the reasons for the selection of the field of study are briefly outlined. That work is now fairly under way, and as this report covers the official beginning of a new program of operations, it appears desirable to state in somewhat more detail the areas in which we expect to work, our interests and our objectives.

The broad field of interest of the Department has for many years been aboriginal American history. Owing to its apparent isolation from the Old World before Columbus, America has long been recognized as a field of outstanding importance for the study of primitive peoples and their cultures. It is probable that greater opportunities for significant accomplishment occur nowhere in the world.

History is a term that may be used in a variety of senses, often being limited as to subject matter. As is suggested by the use of the word aboriginal, what is meant here is human history. This can be defined as the relation of man to nature and of man to man. Man is the protagonist, but his actions are intelligible only against the background of nature and society. Indeed, the very essence of the drama is the interplay of man and his environment, of man and the rest of his kind. The complete story of aboriginal man in America is, then, our wide field of interest, and our broad objective is to contribute as much as possible to the unfolding, the understanding and the telling, of that story.

It is quite obvious that so vast a field is subject to attack by no single discipline, much less by any one institution. It is nevertheless felt that our interests should not further be limited. Even though we deal directly with but one section of one small chapter, we are concerned with the entire story, and the section with which we deal is significant only as a part of the whole. Only by having such wide objectives in mind are our researches, often highly specialized, kept in proper focus.

As our ultimate concern is with the whole range of aboriginal American history, we naturally look, in selecting problems of the first importance, to those areas that seem to have been of most effect in shaping the course of history, and culture. These are the areas of high civilization, the two principal foci of which are the Andean and the Mesoamerican. There flowed the main currents of history, currents that exerted far-reaching influences. In each of these regions there seems to be a richer continuous column of cultural stratigraphy than anywhere else. Either area constitutes a very large field of interest, far too large for attack by any single institution; but before proceeding to the specific program of researches to be undertaken by the De-

partment, we may first give some attention to the aims and methods of archaeology.

Archaeology is primarily a study which extends our knowledge of human history into periods with little or no documentation by written records. Though it contributes to many disciplines which are concerned in social and humanistic studies, it is not itself committed to any specific approach to the solution of problems of human behavior, and its relevance to these problems is limited by the nature of its material, chiefly the physical remains of man's past activities. From time to time, workers in other disciplines have attempted to direct the attention of archaeologists specifically to their problems and to shape archaeological methods to their objectives. Such efforts on the whole have not been successful; it is the nature and distribution of archaeological remains which determines sound procedure, and the concentration on a single objective, or the sole pursuance of a given hypothesis, results inevitably either in wasteful destruction of evidence pertinent to other subjects, evidence which may never be duplicated, or in the incidental and time-consuming accumulation of a vast body of irrelevant material, which must in any case be dealt with in some way. Since an archaeologist cannot eliminate or ignore irrelevant material and his selection of evidence is limited to the location of his excavations, he is constrained to pursue simultaneously a wide variety of problems. The directing aims of his programs must be founded on broad considerations than are programs in disciplines which can proceed by successive establishment of specific propositions.

Archaeology, then, cannot and should not direct its methods specifically toward obtaining material for the use of certain other disciplines. Its direct obligation is the study of human history in the widest sense. It has nevertheless the contingent obligation of making available to other studies material that may be of value to them, and of making it available in the fullest form possible, without loss or destruction of material germane to archaeology and to still other disciplines. In point of fact, the two obligations seem to run parallel, for in fullness of detail and in complete interpretation of materials both purposes are served and the eventual aims of archaeology are attained.

It is quite obvious that the chronological and geographical ordering of the bare bones of a bygone culture does not complete our obligation toward the study of human history. Nor does the discovery of the fact that this or that culture was in contact with its neighbor or some distant culture. This sort of information articulates the skeleton, but it remains a skeleton. Inferences that may be gained in regard to social and political structure are valuable. Such knowledge begins to explain how the skeleton was put together and

how the joints worked. We cannot stop there, however, for our objectives are not attained by knowing how man did things; we wish know why he did them. We are concerned with the flesh that clothed the skeleton, the blood that kept it alive, the nervous system and brain that directed it. We wish to know culture as a living, functioning entity, and to do so we must know something of its intellectual content.

So complete an understanding of a past civilization is most likely to be attainable when a certain amount of written record has survived. This is well exemplified in the Classical and the Egyptian areas in the Old World. In America no comparable body of written record exists. Such material is not wholly lacking, however, the hieroglyphic texts and codices of Mesoamerica being examples.

The Department has selected the later stages of the preconquest history of Yucatán as the most fruitful area for our researches. The existence of a native literature in the form of the Books of Chilam Balam, the Ritual of the Bacabs, and the Maya codices, a literature that concerns the period in question and that will supplement the findings of field archaeology and the historical records of the conquest, is a large factor in making this choice. In selecting this field there is the further advantage of tying our problems in with those of the Mexican mainland, for there is every indication that the late history of Yucatán was deeply affected by invading peoples and cultures from highland Mexico.

The foregoing gives a general picture of the area in which the Department plans to work. Let us be more specific. Our immediate field, as was stated, is the later stages, roughly five centuries, of the preconquest history of Yucatán. We propose to bring to bear on a group of related problems the combined evidence of historical records, native literature, and field archaeology, and to test historical, literary, and archaeological evidence against one another and thus contribute a critique of basic methods and interpretations.

The major aspect of the program is the archaeological field work. Present knowledge allows us to postulate three periods in the later stages of Yucatecan history. These may be termed, in chronological order, 1. Period of Foreign Domination, 2. Period of Maya Resurgence, and, 3. Period of Disintegration. We possess considerable knowledge of the archaeology of the first period, but very little of the last two. Our field efforts at the outset, therefore, will primarily be concerned with the later periods. In describing the work contemplated, it will of course be understood, we are presenting no more than a blueprint, to be changed and corrected as the results of research dictate.

Historical and literary sources and superficial archaeological information all indicate that the city of Mayapán was the dominating influence in Yucatán

during the second period enumerated above. It is the logical place to search for information concerning that period, and the major weight of our effort will at first be there. What is known of the site suggests that excavation and above-ground survey be directed more toward secular aspects of life, types and arrangement of dwellings, household equipment, settlement patterns, and the like, than toward a study of the ceremonial remains that have received so much attention at other Maya centers. It is desirable, however, that all aspects of the life of the community be kept in mind.

Certain coastal areas of Yucatán were of importance at the time of the conquest, and it is believed they were important during the period of domination by Mayapán. The remains of these regions should bridge the two periods with which our field work is primarily concerned and should give breadth and depth to our findings. As these areas are archaeologically little known, exploration and superficial testing are needed: first, to provide a composite picture of the region; second, to determine the locations for any further testing that may be advisable.

Historical records and the native literature provide us with a large list of centers of native population of varying importance at the time of the conquest, and with considerable information concerning the location and extent of, and conditions in, the various native provinces. We thus are able to select several sites which were important during the final period of the preconquest history of Yucatán and which at the same time have a representative distribution among the native provinces. Excavations at such sites should throw light on the final period of preconquest history and should establish contact with matters of historical record.

In the preceding pages we have outlined the areas in which we expect to work. Let us now turn to a review of the recent activities of the Department. As noted at the beginning of this report, the period under consideration witnessed the official start of our new program of researches. It might be thought that the period was divided into distinct parts, the first concerned with the work of the old program, the second with that of the new. That is in a sense true; for after January 1 emphasis clearly shifted. On the other hand, any such change of direction is not entirely abrupt. It is rather a wide swing around the marker, a transition rather than a complete cessation followed by new beginnings. All projects do not end on the same day, nor would it be orderly or profitable for everyone to initiate new researches at the same moment. For some time past the work of the Department has been moving little by little into channels leading to new objectives. At the same time the gradual completion of activities initiated under the earlier program has been going on. This latter phase of the work may be covered briefly.

Certain administrative matters merit recording. It was noted in the last annual report that the headquarters we had maintained at Copán, Honduras, had closed. This terminated for the time, and it is hoped only temporarily, a fruitful and cordial relationship with the government of that country. Our most sincere thanks are due to the Minister of Education of Honduras and to the many officials of that country who cooperated so wholeheartedly with the Institution.

The end of 1950 saw the termination of our contract with the Government of Guatemala, a move made necessary by the change in scene of our activities. It is with honest regret that we end for the time being an extremely productive and friendly relationship with that government, and is our hope that we may at some future time resume our work there. Our sincere thanks are due to the Minister of Education of Guatemala, to the Director and staff of the Institute of Anthropology and History, and to the many officials and civilians who collaborated so effectively with the Institution. R. E. Smith was in charge of closing the headquarters maintained by the Department in Guatemala since 1926. By the end of December 1 all archaeological materials in our possession had been turned over to the National Museum of Archaeology and Ethnology, equipment that was not of further use had been disposed of, and useful equipment and records had been shipped to Cambridge or to Mérida, Yucatán.

As has been noted in recent annual reports, the staff has for several years been concerned primarily with the preparation of reports covering the results of earlier work. These activities have resulted in a large number of manuscripts in various stages along the way to publication. This has placed a heavy burden upon the editor of the Department, and the process of preparing this material for the press will continue for some months in the future. A detailed report by Margaret W. Harrison covering publications by the staff will be found in succeeding pages.

An activity of the past season, in part assignable to earlier work, in part to current work, was the ordering and disposal of large archaeological collections from Yucatán, collections that had accumulated over many years. This task was directed by Shook and is described below in a report by him and Proskouriakoff. Though much of the material had previously been recorded, a considerable amount of photographing and drawing of specimens remained to be done, and all the material had to be sorted and arranged for eventual disposition. That this was no small task is witnessed by the fact that it occupied most of the time of two members of the staff and part of the time of two others. By the end of the season all objects suitable for museum use had been turned over to the Mérida Museum, a collection of skeletal remains had been depos-

ited with the local office of the National Institute of Anthropology and History, and the extensive sherd collections had been arranged and stored so as to be easily accessible for study purposes. A type collection of sherds has been sorted out by R. H. Thompson, and all that remains in the handling of this earlier material is the matching of this collection in sufficient lots to provide sherd samples for various museums in Mexico, Guatemala, and the United States, a relatively short task.

We may now turn to activities concerning our new researches. Again let us note certain administrative matters. In July 1950, the staff of the Department met in Cambridge to discuss the work of the following field season. Although the broad outlines of our future work were by then well understood, decisions concerning location and type of facilities, priority and personnel of projects needed to be reached. At the same time, certain specific historical problems that seemed to offer good hope of solution through field work were outlined, the result being a most interesting and helpful document for staff use. In regard to facilities, it was decided that office, laboratory, and storage space should be established in Mérida, and that field quarters should be constructed at the village of Telchaquillo, close by the ruins of Mayapán. Strömsvik was put in charge of these operations, as well as of arrangements for the purchase and shipment of the not inconsiderable quantity of supplies and equipment needed.

Prior to this meeting of the staff, negotiations had been entered into with the Secretariat of Public Education of the Government of Mexico, through the National Institute of Anthropology and History, leading to a 5-year contract under which the Institution might operate. This contract reached final form and was executed near the end of October. Shortly thereafter Strömsvik proceeded to New Orleans, arranged for the purchase of supplies and equipment, and then continued to Yucatán. It at once became apparent that office facilities of the right type were not easily obtainable in Mérida, but by December Strömsvik was able to report that suitable quarters had been found, both in Mérida and in Telchaquillo, and that general terms of leases had been arranged. Pollock consequently flew to Yucatán early in January, examined the properties in question, and took steps to conclude leases.

At this point our operations became handicapped by the difficulty of obtaining many of the items of supplies and equipment on order in New Orleans. Although such delays resulted in our not receiving the major part of our shipment until near the end of the field season, Strömsvik proceeded with construction at Telchaquillo, carrying that work as far as possible with the resources at hand. Shook, who had taken charge of the Mérida office shortly after the lease was concluded, made steady headway with the installa-

tion of facilities there. This work was virtually completed by the end of the season. Strömsvik, with necessary supplies in hand, is continuing operations during the summer and autumn of 1951, and there is little question but that by the beginning of next field season the quarters will be in readiness.

In last year's annual report it was noted that the Department had undertaken the mapping of the ruins of Mayapán. This project was brought to completion by midwinter, and a preliminary edition of the map is now in process of publication. During the past season photographic copies of these sheets were available to the staff and were an important aid in the archaeological work carried on at the site. The information provided by this map already has affected our thinking relative to the character of the ruins, problems presented, and procedures leading to the solution of problems. A report by Morris R. Jones on the survey and base map at Mayapán will be found below. The Department wishes to express its thanks to the U. S. Geological Survey for its co-operation in this project.

The major effort in the field last season was Ruppert's and A. L. Smith's archaeological survey of Mayapán. The portion of the map that had been completed the previous year had brought out the fact that here, for the first time at any Maya site explored, was a wealth of what appeared to be the remains of dwellings. Jones had estimated 3500 structures within the walled area, and there was reason to believe that the greater proportion consisted of dwellings proper or auxiliary structures. So little is known of the humbler aspects of Maya life and society, the great weight of previous research having gone into the public, religious, and in general hierarchic and frequently esoteric expressions of that culture, that the existence in such number of these relatively simple structures immediately pointed up an interesting and important area of research.

Ruppert and Smith devoted virtually the entire season to an above-ground survey of building remains at Mayapán. The number of remains and the variations in plan and arrangement, variations that may prove to be significant, introduced a problem not only in recording but in the subsequent handling of the recorded material. A system of cards showing scale drawings of plans and carrying other relevant information was adopted. It is thought that as the work progresses and material accumulates, these loose cards can be sorted and arranged to follow any desired scheme in the process of analysis.

An interesting allied research is a study of the numerous stone walls that run through the site. These suggest boundaries of properties, but their function will remain in doubt until the relation of walls to house structures and terraces, and of one wall to another, is

brought out by careful plotting. The study is important because it has a bearing on systems of land tenure, population estimates, and other such problems fundamental to an understanding of the life of the people. Our work at Mayapán is fairly begun, and interesting problems, only a few of which are touched upon here, are unfolding rapidly. We may now review our researches in a different area in time and space.

The city of Mayapán is thought to have been abandoned, or at least to have ceased to function as a governmental and administrative center, around the middle of the fifteenth century. Less than a century later, during the two decades lasting approximately from 1520 to 1540, the invasion and final conquest of Yucatán by the Spanish took place. Roys has assembled much documentary material dealing with this period, but little attention has been paid to the material remains. Working closely with Roys, R. H. Thompson carried on investigations concerning the archaeology of this immediately preconquest and early postconquest period. Brainerd's work of a decade ago, not directed primarily to this problem, had produced relatively few remains from these cultural horizons, and he was unable to identify what might be the typical ceramics. The work of the past season again met with negative results. In his detailed report below [Chapter 6.11 this volume], Thompson offers a tentative explanation for our failure in this search. We shall continue our efforts toward a solution of the problem.

It is vexing to have this short span of time that bridges the gap between a purely native cultural tradition and the beginning of a mixed Old World-New World tradition virtually unrepresented by cultural remains. Until we have a better understanding of this final episode of native history in Yucatán, we cannot hope clearly to comprehend the impact of European civilization upon the aboriginal culture, to know what traditions persisted, what were displaced, what blended. Knowledge of this sort should, moreover, enable us better to visualize the similar process occasioned by the inroads into Yucatán of foreign ideas, if not actual populations, from the Mexican mainland, a process that apparently had been going on for centuries prior to the arrival of the Spanish. We are here dealing with the dynamics of culture; it presents intriguing problems.

As noted on an earlier page, Shook and Proskouriakoff were primarily engaged in the putting in order of archaeological collections that had resulted from past work of the Institution in Yucatán. They did, however, find time to carry on some reconnaissance in areas which either from documentary information or from superficial archaeological knowledge were thought to hold promise of providing information important to the central researches of the Department. Their trip

along the west coast of the peninsula is of special interest because this is a region that seems almost surely to have been traversed by any route carrying contacts between Yucatán and the mainland to the south and west. Proskouriakoff was also able to look into the problem of improving our photographic record of the sculpture, mostly bas-relief, at Chichén Itzá. The greater part of this sculpture is architectural, and it frequently occurs in locations that place difficulties in the way of field photography. The sculpture is important in being the one considerable body, so far known, of art of the period of foreign influence in Yucatán. There is a striking opportunity here for differentiating between Maya and foreign cultural traits, as depicted in the sculpture, and there is the hope of tracing the foreign elements to their source or sources.

During the earlier part of the period under review, and before we had officially ceased operations in Guatemala, Shook was able to advise and assist the Institute of Anthropology and History of that country in a most interesting discovery at the ruins of Kaminaljuyú. His report brings out the fact that we must revise our ideas as to the beginnings of formal architecture in that area.

Shepard devoted part of her time to the preparation and virtual completion of a book on ceramics for the use of archaeologists. The purpose and plan of this book is outlined in *Year Book* 46 [Chapter 4.15]. It is awaited with keen expectation by archaeologists. On the research side, Shepard undertook a review of our present knowledge of Yucatán ceramics. Her report discusses certain technological aspects of the pottery. She has particularly concerned herself with the recognition through laboratory analysis of ceramic samples as products of local specialization, or of intra- or extra-regional trade. In an area where much of the pottery is macroscopically similar, this approach is of great importance. There is also the problem of tracing imported pieces to their sources, thus drawing lines of trade and giving information on relative chronology. Shepard has not yet had available collections of pottery sufficient to furnish more than an outline of the problem. As our work progresses, there is good reason to hope this line of research will be highly informative.

J.E.S. Thompson has begun the compilation of a dictionary of noncalendrical Maya hieroglyphs, and in doing so has stepped where others feared to tread. It is a huge task, not immediately rewarding, but the result should constitute a tool of immense value not only for Thompson's studies, but for all studies concerned with the interpretation of Maya hieroglyphic writing. Thompson also has served as assistant editor of *American Antiquity*, writing the "Notes and news" sections dealing with Middle America, preparing lists of new

publications on that area, and acting as consultant on articles and reviews submitted for publication.

Roys, who is engaged in post-retirement studies, has completed a manuscript dealing with settlements in Yucatán at the time of the Spanish conquest and the subsequent destruction of the native architecture. This work is now in press. As previously noted, Roys has co-operated with R. H. Thompson in his researches dealing with the conquest period. A third activity is concerned with the historical content of the katun prophecies in the Books of Chilam Balam. These form part of our none too abundant documentary sources for the preconquest history of Yucatán. The present report is, of course much abbreviated. It is hoped that further research will result in a critical text with translation, notes, and an essay.

In this period of exceptional administrative activity, the Director has been forced to spend most of the time at his desk. His brief trip to Yucatán early in January 1951, previously referred to, was devoted almost entirely to business matters. Later in the season, from the middle of April until the end of May, Pollock was again in Yucatán and was able to give part of the time to a study of the ruins of Mayapán. One of the purposes of this work was to gather material to serve as background for staff discussions, held in Mérida the end of May concerning operations for the next field season. In his survey of the ruins, Pollock was struck with the amount of information available from surface examination or relatively minor excavation. He was also impressed with the apparent opportunity to learn something of the humbler aspects of aboriginal culture in contrast with the ceremonial, a situation that has been referred to several times in this report. These conditions are important in planning future work. It would seem that at the outset of full-scale operations at Mayapán we should avoid excavation of large structures, confining ourselves to above-ground survey and to relatively small excavations in a number of promising locations. Much of our thinking, moreover, should be directed toward family husbandry, land tenure, settlement pattern, trade, and other such fundamental economic and social aspects of the aboriginal community. This is not to say that the religious and political life of the people is not interesting and important. It of course is; but the city of Mayapán seems to offer exceptional opportunity for a study of the less spectacular phenomena of native culture as it existed shortly before the impingement of European civilization.

It is with deepest regret that we report the death on January 1, 1951, of Robert Hayward Barlow, a Carnegie Institution Fellow working with this Department. In his thirty-third year when he died, Barlow had made a contribution to our knowledge of Mesoamerican prehistory that already was impressive.

There have been few scholars, if any, who have commanded such knowledge of the protohistoric period of the native civilizations of Mexico. At the time of his death he was extending his mastery of the subject to include the Maya. Brilliant, with an insatiable thirst for knowledge, he drove himself beyond the limits of a none too robust physique. His death is a signal loss to the whole field of Mesoamerican prehistory and is a blow to the researches of this Department that ill can be afforded.

The retirement of A. V. Kidder on November 1, 1950, as Chairman of the Division of Historical Research terminated an association with Carnegie Institution of over 25 years. Coming to the Institution in an advisory capacity in 1924, he was appointed Research Associate in 1926, Associate in charge of archaeology in 1927, and two years later Chairman of the newly created Division of Historical Research. As might be surmised from this administrative grouping of the various historical activities of the Institution, it was Kidder's guiding principle that any true understanding of human history can come about only by the coordinated efforts of numerous disciplines. He promptly put this principle into practice by organizing a program of allied researches. As time passed, economic pressures forced the Institution to look more to co-operation with other agencies than to direct financing of so broad a program; but Kidder's advocacy of a multi-sided approach to the solution of historical problems remained a potent stimulus to the many researches, both within and outside the Institution, that have gone forward in Mesoamerica over the past 20 years. This is not the place to review Kidder's many and brilliant accomplishments. Indeed, it would be premature to do so in any place, for we have every expectation that his new status will little alter the course or effectiveness of his researches. From the point of view of the Department, our regret at his official departure is tempered only by the hope that his sage counsel and sound advice will continue to be available to us.

1.41.

H.E.D. POLLOCK

Department of Archaeology

YB 51:235-243, 1952

In the previous annual report we noted the beginning of a new program of researches. It will be recalled that

the locus of our studies, in time and space, was the later stages of the pre-conquest history of Yucatán. Of the several approaches to be employed, archaeological field work was the central one. It was further noted that the ruins of Mayapán would be the scene of our initial efforts.

During the past season these plans were rather closely followed. Most of the staff of the Department were stationed at our base camp at Telchaquillo, adjacent to the Mayapán ruins. In this first period of full-scale operation it was felt that excavation should progress with caution, and that our procedure should be one of intensive archaeological survey using the topographic map of the site that had been completed the previous year as a means to that end. A broad picture of the problems that face us and of the critical areas for investigation has emerged from this study. It will come as no surprise that this exploratory work has raised more questions than it has solved. In the succeeding paragraphs we shall touch upon the wider aspects of our findings and point to some of the problems.

Reconstructions of Maya history have, of course, changed over the years. Such shifting and sifting and rearrangement of ideas is of the very essence of research. It is further true that at no particular time in the course of our studies will there be unanimity of opinion in these matters. At the present stage of thought, nevertheless, few people will differ with the broad chronological and cultural division of the history of the Maya peoples into the Preclassic, Classic, and Postclassic Periods, although the divisions will be differently named by different students. There will also be general agreement that we are dealing with a span of time that at least covers the Christian Era up to the European conquest of the New World and that may extend an indeterminate distance into times before Christ. There will be wide differences of opinion as to subdivisions of the larger periods, as to association of cultural periods in different geographical areas, and as to any precise chronology. Concerning no period probably is there greater diversity in our ideas than concerning what we have termed the Postclassic. This was the era that followed the apparent breakdown of the early system of exact dating in the Maya calendar. It is the period with which our present studies are directly concerned.

At this point it seems well to outline, as basis for discussion, a widely accepted reconstruction of Yucatán history during Postclassic times. In our previous report [Chapter 1.40] we referred to a Period of Foreign Domination, a Period of Maya Resurgence, and a Period of Disintegration. These three divisions, in the order given, constitute the Postclassic Period in Yucatán. Although he uses a different terminology, the scheme in general follows the ideas of J.E.S. Thompson

(1945). His chronology, in round figures, is Foreign Domination A.D. 1000–1200, Maya Resurgence A.D. 1200–1450, Disintegration A.D. 1450–1540. The Period of Foreign Domination represents the time when invaders of Toltec culture from highland Mexico presumably held sway over Yucatán, their personal base being Chichén Itzá. The Period of Maya Resurgence was that during which older, native ideas were supposedly reasserting themselves over the foreign practices of the Toltec, Mayapán reportedly being the governmental center of the northern part of the peninsula. The Period of Disintegration followed the overthrow of Mayapán, involving the end of central authority and the breakup into numerous warring states. This last period was in a sense an extension of the preceding one in that the resurgence of Maya ideas and customs is presumed to have continued. Theoretically, principal settlements of the time should have been the capitals, several of which are known today, of the various states, but up to the present the remains of this particular period have not been identified at those sites or elsewhere in Yucatán.

We may now turn to our findings of the past season and focus these findings against the background sketched above.

It is already clear from our relatively small sampling of the pottery of Mayapán that people lived in or around this site from Preclassic times, through the Classic Period, and into the Postclassic at least through the Period of Maya Resurgence; as was noted above, the final Period of Disintegration remains archaeologically unknown. This evidence of a long span of occupation agrees with Brainerd's findings of a decade ago [Chapter 4.10]. Pottery of Preclassic times occurs as little more than a trace, and pottery that might date from the early part of the Classic Period is relatively rare. No remains of buildings recognizable as belonging to either epoch have been found.

It was during the later phases of the Classic Period that Mayapán seems first to have become a center of any importance. In Yucatán this period is known as that of the Puuc, taking its name from the hill area along the border of the States of Yucatán and Campeche, in which the greatest concentration of remains of the time is found. It was a time of great vitality, and architectural remains of characteristic Puuc style occur in huge numbers in that area and sporadically throughout the northwest part of the peninsula. The period might be, dated from A.D. 700 to A.D. 1000, although there is little basis for any exactitude in chronology. The era comes to a close with the supposed abandonment of the hill area and the end of the Puuc architectural style. At Mayapán we find Puuc Period pottery, little in proportion to that of the later, great period of the site, but nevertheless in appreciable amounts. Pos-

sibly more striking are the widespread building remains. Not a single standing structure of the period has so far been found, but building stones, both carved and plain, fashioned in the typical Puuc manner occur all over the ruins, lying individually and in groups, and re-used in later construction. Fortunately, in many cases the stone work of the period unmistakable and can be identified with little hesitation. There is also the possibility that some of the stelae and both pieces of sculpture at Mayapán may be of this time.

We find the opening phase of the Postclassic Period, what has been termed the Period of Foreign Domination, the Toltec Period at Chichén Itzá, virtually unrepresented, or at best but slightly represented at Mayapán. This is surprising, not only because historical sources suggest that the city was then of some consequence, but because the site so clearly had been occupied in the immediately previous period. Nevertheless, no example of architecture or of sculpture can surely be assigned to this epoch. A few such remains are reminiscent of Chichén Itzá, the type site of the period, but even in these cases there is sufficient difference in execution to question their being products of the time. Unfortunately, we are unable to present a clear picture of the evidence regarding pottery. Two imported types that presumably are indicators of this period occur, or at least are recognizable, in trace amounts. They are conspicuous more by their absence than by their presence. No ceramic stratigraphy has thus far developed at Mayapán, and in our present state of knowledge we are unable to sort out the local Yucatán pottery that might be assigned to the period.

Our next division in time, the Period of Maya Resurgence, seems quite-clearly to include the rise to power and greatness of Mayapán. Most, if not all, of the standing or partly standing architectural remains, much of the sculpture, and the vast preponderance of the pottery belong to this time. There are faint indications at Mayapán that this was not an altogether static period, that culture was undergoing changes reflected in the remains, and that we may be able to divide the period into phases. Little, however, can be said at present on this subject.

Let us summarize in a few sentences the picture we have sketched of our preliminary findings, and then turn our attention to a broader scene. The peoples of the Preclassic and Early Classic Periods left but a trace of their handiwork at Mayapán. The Puuc culture, presumably of Late Classic Period, is clearly represented in architecture and pottery. This seems to have been the time when Mayapán first became a center of any importance. During the first stage of the succeeding Postclassic Period, the Period of Foreign Domination in Yucatán, Mayapán appears to have been of little or no importance; indeed, there is even the sug-

gestion of a break in 'cultural continuity at this time. The Period of Maya Resurgence, possibly divisible into phases, witnessed the greatness of Mayapán. This is attested by the building remains and by the wealth of pottery recovered. It has been noted earlier that no archaeological remains, at Mayapán or elsewhere in Yucatán, have surely been recognized as belonging to the final Period of Disintegration.

Turning to the wider scene, the history of northern Yucatán, we shall confine ourselves primarily to the later stages that together form the Postclassic Period, the times with which our studies are directly concerned. We have already described briefly the immediately preceding, presumably late Classic, Puuc Period, and pointed out that, although the home area of this culture contains by far the greatest concentration of remains of the period, traces of the characteristic architectural style occur well to the north and in general may be said to be spread over the northwest quadrant of the peninsula. In the region north of the hills, there also occur architectural forms strikingly different from those of the Puuc. In certain instances these underlie the Puuc remains. There is some reason to believe on stylistic grounds that these ruins are of the Early Classic Period, but their date is by no means certain, and there is the possibility that they are Late Classic, conceivably contemporaneous, or in part contemporaneous, with some of the Puuc ruins in the hill region.

The eastern extension of the Puuc culture is not well known. Architectural forms that vary from a general similarity to those of the Puuc to virtual replication occur at Chichén Itzá. This is the approximate eastern boundary of this architecture as now known, but the characteristic pottery has been found farther east. The northeastern part of the Yucatán peninsula is not well explored, and there is ample room for future discovery. Should present indications that Puuc styles of architecture do not occur in the area the confirmed, we hope to learn what building forms were being used at this time, and what are the stylistic affiliations to other areas.

It will be remembered that the Early Postclassic was the Period of Foreign Domination, according to the scheme we have been following; it has also been called the Mexican Period and the Toltec Period. It was at this time that Chichén Itzá seems to have reached its apogee the greatest structures there being assigned to this epoch. Although the concept of a foreign element in Yucatán arises in part from documentary and historical sources, the primary evidence pertaining to the period under discussion consists of the architectural and sculptural remains at Chichén Itzá. These exotic forms suggest ideas, religious beliefs, and social organization that are not Maya. The amazing similarities

to the art and architecture of Tula, Hidalgo, moreover, leave little doubt as to, the identity of the invading culture.

The archaeological evidence is bolstered by documentary and historical references associating Chichén Itzá with what seem to have been non-native peoples, although the time of the association is open to doubt. There remains the question of how thoroughly the foreign culture penetrated the social fabric of the city and its environs, and whether the non-Maya elements affected only the priestly and ruling group or were taken over by the commoners as well; but the presence of a foreign culture at Chichén Itzá seems indisputable.

In northern Yucatán, we find no such evidence. On the contrary, we are presented with a situation closely parallel to that at Mayapán. Outside the immediate area of Chichén Itzá, with the exception of a few traces, and those of questionable identification, there is not a single ruin so far as we know that exhibits architectural or sculptural remains that can be identified as like those of the type site or as being of this period. We do not know at present what is the pattern of distribution of pottery. As a result of his work of some years ago, Dr. Brainerd seems to think that the typical pottery of Chichén Itzá of this period is by no means confined to that site [Chapter 4.7 this volume].

We have, then, a most puzzling picture of a single great city I that appears to have exerted little or no influence on the arts and handicrafts, with the possible exception of pottery, outside its immediate neighborhood. The situation becomes no less puzzling when we consider the vitality of the Chichén Itzá culture of this time. Taking our evidence at face value, we are forced to picture a great, thriving city existing in a sort of cultural vacuum. Whether this be interpreted as meaning that human effort from all parts of Yucatán went into the building of Chichén Itzá, to the exclusion of local works, or that the dominance of that city over the peninsula was so great that nowhere else were people allowed or able to express themselves in the new architectural forms, we are presented with a picture that lacks reality. The presence elsewhere in Yucatán of pottery of a sort made at Chichén Itzá at this time, moreover, would not alter the situation. This fundamental and simple handicraft presumably would continue no matter what was taking place in the higher expressions of art and architecture.

Here is an interesting problem. The nature of the question and its answer hinge upon our chronological framework and how we interpret events during the Period of Foreign Domination. How widespread in Yucatán, and of what effect upon the social structure was foreign influence? How rapidly did the conquest, if in fact there was a conquest, proceed? Are we correct in assigning the foreign penetration to a period

following that of the Puuc? The greatness of Chichén Itzá, expressed in its architectural remains, and certain historical references to the dominant role of that city at a certain period in history have led many people to believe that a great part of the peninsula was under the sway of the foreigner. Yet we have just noted that the archaeological remains, as known today, do not bear this out, unless we think of the invasion as a military conquest of such intensity that virtually all important effort in architecture and sculpture ceased outside Chichén Itzá. It should be remembered that we are not dealing with a period of a decade or of a generation, but with one of approximately 200 years.

There are, of course, a number of ways in which we can modify our ideas in respect to the political and cultural events of the time. We might suppose that the conquest of Yucatán was relatively benign, a supposition that has little basis in the light of the militaristic character of the Chichén Itzá sculptures. We might assume that the invader exerted political control over the country but had little effect on the native culture. This also is difficult to believe because of the warlike character of the foreigner and the length of time involved. In the case of either of the above suppositions, we are plagued with the riddle of no material remains, except possibly of pottery.

A position that seems more tenable is to assume that the invader and his culture were confined to the Chichén Itzá area or possibly the eastern part of the peninsula. This would not be unlikely if the foreign elements entered Yucatán when the Puuc culture was still vital. In any event, the older forms of art and architecture might have continued in use in the west. We then become involved, however, in further questions: Precisely what, for example, in time and culture, does the Puuc Period represent? When did it terminate? When was the Puuc area abandoned? Did the characteristic architectural style continue in use elsewhere, particularly in the north? These questions, and many more could be formulated, are subject to answer only by further exploration, excavation, and study of existing data. Our purpose here is simply to note that the apparent absence at Mayapán of the remains of an important and critical period has led us to look further and, in so doing, to question the time and the nature of certain events in the history of Yucatán.

The next division in the chronological framework we have been using, the Period of Maya Resurgence, presumably saw the rise to power of Mayapán. It is often referred to as the Mayapán Period, that city being the type site. Elsewhere in Yucatán, notably along the eastern coast, there occur architectural remains that stylistically and in method of construction are very similar to those of Mayapán. Certain presumably late constructions at Chichén Itzá may well belong to this

period, particularly to its earlier part. What little is known of the pottery seems to confirm the placing of the East Coast and late Chichén Itzá remains in this general period. Other occurrences in Yucatán of constructions and pottery of Mayapán type are sporadic and often questionable as to identification.

Although one might expect more numerous traces of the culture of these times, the lack of evidence does not appear comparable to that concerning the preceding period. Structural design of buildings was inferior to that of earlier times; disintegration undoubtedly proceeded rapidly, and little was left comparable to the earlier distinctive stone cutting and typical architectural elements. There is also the suggestion that sizable ceremonial structures were not being built in any numbers, and small constructions, domestic or religious, are not readily spotted in the course of exploration. Possibly of even more significance in this connection is the fact that we are dealing with a period of cultural decadence. It would not be unexpected that in such times the effort that went into religious or public monuments might largely be confined to the central seat of authority or, at most include a few of the larger provincial centers.

There has been a tendency among Mayanists in recent years to divide what we have called the Period of Maya Resurgence into two subperiods, the division falling around the middle of the fourteenth century. It has been mentioned that at Mayapán there are faint indications that the remains of the principal occupation of the site may reflect two cultural phases. Such a division would seem better to suit possible ceramic and architectural relationships between Chichén Itzá and Mayapán. Our evidence at the moment is much too fragmentary to draw conclusions, but it is an idea with sufficient basis to merit attention.

A matter of equal importance with chronology is the character of the culture at any time. The two periods we have primarily been discussing have been labeled Foreign Domination and Maya Resurgence. Though these terms are in a sense no more than convenient tags, they carry cultural or political connotations and deserve examination in that light. The Period of Foreign Domination has been discussed, and the appropriateness of the term has been brought into question. The designation of the second period, Maya Resurgence, is a sequel to the first, the implication being that foreign forms and practices gave way to older, native ideas. This has also been called the Period of Mexican Absorption, with much the same implication. Some students have preferred to label both periods simply, as Mexican, not recognizing at least in designation, the idea of a return to native Maya traditions.

The concept of a Period of Maya Resurgence or Mexican Absorption is based on historical, ethnologi-

cal, and linguistic evidence at the time of the Spanish conquest and on the absence of art, particularly sculpture, like that which flourished at Chichén Itzá in the preceding period. There is also the evidence of presumably late art at Chichén Itzá, and possibly in the East Coast ruins, showing more Maya elements than the Toltec art of that city. On the other hand, the great preponderance of building remains assigned to this late period are not of Maya, but of so-called Mexican, style. Though the architecture differs from that of Chichén Itzá of the preceding period, the style could well be a degeneration of those forms and certainly is more foreign than Maya. Indeed, in respect construction this late architecture is farther from the Maya than are the earlier Chichén Itzá forms. The question arises, then, Are we correct in thinking of this period as time of general resurgence of Maya culture throughout Yucatán?

The answer is clearly affected by our ideas concerning the preceding period. If the foreign culture was not generally accepted in Yucatán but was confined to the Chichén Itzá region, we can hardly speak of a Maya resurgence except as applied to that city. Even if the invaders controlled a larger area, there is considerable question how much of their culture was taken over by the Maya, and whether the civilization of Yucatán was more foreign then than in later times. Indeed, one can take the position that foreign cultural elements more common in the later period than the earlier. These questions are not now answerable with any certainty. The problem of relative chronology, raised above, is of paramount importance. The conclusion we reach is simply that, taking the hardcore of evidence now available, one well can question certain widely accepted beliefs concerning the late preconquest history of Yucatán.

Our idea in the foregoing discussion has not been to sketch the history of those times or to present all arguments and each alternative. The intent has been to indicate on a broad scene some of the problems with which we have to deal and the status of those problems at the beginning of our present program of research. We now may turn to a review of certain staff activities of the past year. Detailed reports by members of the staff will be found following the present section.

The off-season period, July through December, was used by Strömsvik for the construction of our base camp at Telchaquillo. The essential work was accomplished by the first of the year, but throughout the winter and spring Strömsvik was engaged in adding minor conveniences, in adjustment and maintenance of machinery, and in the supply of special equipment for the need of the moment. Experience of a season indicates that the camp is comfortable, convenient, and well adapted to our needs.

In the latter part of November, Strömsvik flew to Honduras to confer with governmental authorities relative to problems concerning the antiquities of that country. He participated in discussions leading to the establishment of an Instituto de Antropología e Historia similar to such bodies in Guatemala and Mexico. Strömsvik has been named Technical Adviser to the Institute, a position involving voluntary services.

It was noted in our previous annual report that the ordering and disposal of large archaeological collections from earlier years had virtually been completed, and that all suitable objects had been put into the hands of the Instituto de Antropología e Historia de México for display in their National Museum or the Mérida Museum, or for study purposes. During the past season R. E. Smith completed the assembling of 10 collections of sherds, each collection indicating, as far as possible, the known types and range of Yucatán pottery. This work had been started the previous season by R. H. Thompson. Three of the collections were made available to the Institute, one to be sent to the National Museum of Guatemala, the other two for use in the National Museum of Mexico and the Mérida Museum. The remaining collections were sent to museums in the United States. With the exception of sherds kept for study purposes, the Department has now turned over to the Mexican Government all archaeological material collected prior to 1951.

During the 1951 field season the work of Ruppert and A. L. Smith on the house platforms at Mayapán [Chapter 40.3 this volume] developed the fact that these dwellings were strikingly similar to the native houses described by the sixteenth century historian Landa. Further confirmation of such historical record occurred this year. Landa observes that the people buried their dead in, or at the rear of, their houses. Excavations of Smith and Ruppert have uncovered several cists or chambers below the floors of dwellings. Interestingly enough, these "graves" were built at the time of the construction of the house, apparently in anticipation of the death and burial of the occupants. That the "graves" were not always used, however, is shown by the fact that in only three of seven examples uncovered were human remains found.

Landa also mentions that "the nobles and persons of high esteem" were cremated rather than interred. Although little work has so far been done at Mayapán in connection with ceremonial or public buildings, Shook discovered below the floor of what apparently was a temple a repository containing the charred bones of adults, children, and animals. This evidence, and that developed by Ruppert and Smith, is suggestive, but at present our knowledge of the burial customs of the inhabitants of Mayapán is fragmentary, much too meager to warrant any general conclusions.

The mapping operations of Jones in 1950 and the archaeological survey of Ruppert and Smith in 1951 disclosed the existence at Mayapán of numerous rough stone walls that may have marked the boundaries of properties surrounding dwellings [Chapter 40.3 this volume]. W. R. Bullard, Jr., a graduate student in anthropology at Harvard University, working with this Department, began a study of these walls during the past season. Preliminary results indicate that the walls occur in residential but not in public areas, and that they may indeed form the boundaries of house lots. Information relative to the pattern of these walls, of passages between properties, and of streets or lanes is beginning to emerge. Fulfillment of the underlying objective of this research, an understanding of city planning, land tenure, density of population, and similar problems, must await further studies.

Proskouriakoff has undertaken the recording and study of the not inconsiderable body of sculptural material found at Mayapán. This has proved to be a disheartening task because of the lamentable condition of most of the sculpture so far discovered. An interesting possibility is that stone figures found in some numbers can be identified as the "idols" reputedly introduced into Yucatán in late times as part of the foreign culture mentioned earlier in this report. The practice of "idolatry" apparently was deeply resented by the older Maya. Proskouriakoff has also begun the study of the artifacts, implements, weapons, minor carvings and the like, of Yucatán.

The existence of another walled city in Yucatán, reported a century ago by an anonymous antiquarian of that country but never visited, so far as we know, by archaeologists, was confirmed by the explorations of Strömsvik and Pollock. Walled cities, few of which are known the lowland Maya area, are important because of certain implications as to the civilization of the builders. The wall at Chacchob, as the site is known, is very similar to that of Mayapán, but the architectural remains and a small sample of pottery seem to antedate the great period of the larger city. This is surprising, walled cities have been thought to phenomena of later times. Further exploration and testing at Chacchob needed to ascertain the period of occupation of the site.

Though Shepard gave a great part of her time to the completion of a book on ceramics for the use of archaeologists, she also was able to continue her researches on the technology of Yucatán pottery. This work has been broadened in scope by the examination of collections of pottery from areas outside the peninsula that may have exported pottery to Yucatán, and by studies of present-day native pottery and pottery methods in Yucatán and Campeche. The possibility that there may be relatively usable sources of clay in

northern Yucatán suggests that the region is particularly suitable to technological research. Certain peculiarities of Yucatán ceramics, such as the high proportion of macroscopically distinguishable wares and the frequent difficulty of obtaining adequate stratigraphy combined with indications of distinctive but little understood regional developments, make the technological studies of special value to our present work.

The large undertaking of compiling a Maya hieroglyphic dictionary, described in last year's annual report [Chapter 6.11 this volume], was continued by J.E.S. Thompson. Work on texts at Yaxchilán, a large site on the Usumacinta River, brought to light interesting material on the brief adoption by that city of the so-called Puuc style of recording dates, a method known to occur elsewhere only in Campeche and Yucatán. During the summer of 1951 Thompson visited Yucatán, Tabasco, and the famous ruins of Palenque in Chiapas. At the latter site he recorded a group of magnificent hieroglyphs in stucco, discovered many years ago in Temple 18 but never previously photographed. Thompson is now engaged in writing a popular book on Maya civilization.

Continuing his researches on the historical geography of Yucatán at the time of the conquest, Roys, operating under a post-retirement grant, spent two months in the field. Of particular note is his identification of what probably was the site of Sinsimato, a large and important town in northeastern Yucatán at the time of Montejó's first expedition early in the sixteenth century.

During the year Joseph A. Hester, Jr., has been appointed a Carnegie Institution Fellow for studies of geographical conditions, with particular reference to agricultural potentials, that may have affected the economy of the ancient Maya. A report on his work, as well as a report by R. H. Thompson, whose fellowship has now terminated, will be found in succeeding sections.

The Mesa Redonda sessions of the Sociedad Mexicana de Antropología, held in Jalapa, Veracruz, the latter part of July 1951, were attended by several members of the staff. Papers were presented by Proskouriakoff, "Scroll patterns (entrelaces) of Veracruz," and by J.E.S. Thompson, "Relaciones entre Veracruz y la region Maya." Shook presented information covering the distribution and chronology of yokes and thin stone heads in areas southeast of the Isthmus of Tehuantepec; R. E. Smith discussed certain similarities between the pottery of Veracruz and that of the Maya area. Shepard presented an exhibit showing the effect of different firing temperatures on different clays, a matter of importance in connection with the classification of pottery.

1.42.

H.E.D. POLLOCK

Department of Archaeology

YB 52:249-256, 1953

In our annual report of two years ago we noted the beginning of a new program of research and outlined the areas in which we expected to work as well as our interests and our objectives. Last year we discussed some of the problems to be met and certain areas that particularly merited investigation. We have now moved into a period of intensive fact-gathering, carried on within the framework of our objectives and directed toward the problems previously formulated. This stage in our researches will undoubtedly continue for several years. It is a period not immediately productive of sweeping conclusions or broad statements of theory, but characterized by the careful ordering, piece by piece, of evidence that through further study and analysis will yield, we hope, the solutions to some of our problems, will on the one hand satisfy, on the other hand stimulate, our interests.

In archaeology the transition from the outlining of problems to the amassing of data relative to those problems frequently means a shift in emphasis from reconnaissance and survey toward excavation. Such was the case in our work of the past season. Intensive excavations were initiated at Mayapán, the focal point of our operations. At the same time, as earlier envisaged, a beginning was made of expanding our researches into areas outside that city. The range of our work, in respect to both character and location, was appreciably greater than in the two preceding seasons.

It has been felt for some time that one of the most promising areas of study at Mayapán is the domestic economy, the way of life, of its ancient inhabitants. At no other Maya site has there been observed such a wealth of remains of simple dwellings. It is natural to believe that other large Maya cities had sizable populations, presumably living in proximity to the ceremonial centers, but the urban character of Mayapán, its population crowded into the area surrounded by the great city wall, and the relatively good state of preservation of the houses make this site particularly suitable for such study.

The work of Ruppert and A. L. Smith has specifically dealt with the above problem. Their survey of building remains in Mayapán is nearing completion. It is now clear that within the urban area of the city, approximately 5 sq km, lie over 4,000 structures, the vast majority of them dwellings and their associated buildings.

Three houses of the larger type were excavated this season. Within the shrine room at the rear of one of the houses were found many fragments of human-effigy incense burners of a type thought to be very late in Mayapán history. Early historical sources contain numerous references suggesting the use of household idols, with the implication that in late preconquest times there had been a trend away from worship in the temples, conducted by the priests, to a more private religion. More excavation is needed before conclusions are drawn, but this evidence is indicative of what we may find.

During the season Ruppert and Smith were able to extend their survey to a study, for comparative purposes, of dwelling-type structures at three of the large centers in the Puuc, or hill, region of Yucatán. This is an area that presumably was occupied and abandoned before the great period of Mayapán. Some 60 examples of houses were studied and plotted at Uxmal, Kabah, and Sayil. As at Mayapán, simple dwellings occur within groups of ceremonial buildings as well as away from them. With the exception of a single type of house at Uxmal, dwellings at these sites do not resemble the typical houses of Mayapán. One may hazard the guess that the vast majority of these Puuc structures are of a different period from that of the Mayapán examples.

Closely allied to the work of Ruppert and Smith was that of Bullard, a graduate student in anthropology at Harvard University, spending his second season with this Department. His project, initiated in 1952, consisted in the study and plotting of the intricate system of ancient property walls that intersect the city of Mayapán. These rough stone walls, which for the most part surround house properties, are in all states of disrepair, frequently are hidden beneath the thorny bush that covers the site, and are easily confused with colonial and modern field walls. The task of following and plotting these boundary markers requires judgment and no small physical effort.

Experience gained during the preceding season made it possible to select an area of the city that held promise of a minimum of destruction of the ancient walls. This was in the eastern part of the site near the small ceremonial center known as Itzmal Ch'en. The area offered the additional attraction of containing several long, narrow lanes, apparently not duplicated elsewhere in the city, formed by parallel walls.

Bullard found that virtually every house or house group had been surrounded by its property wall. This arrangement was so consistent in the area under study that he usually could predict from the topographic map of the site the unit surrounded. There is, every reason to believe that the walls did in fact mark the boundaries of the properties belonging to the houses.

In study of the long lanes, which have a generally east-west direction through this part of the city, it was found that they tended to follow low areas and to avoid house properties. There is thus the suggestion that the lanes are a later work than the houses. The course of these roads indicates that they served as through routes from the more populous central and western sections of the city to the cenote and ceremonial center of Itzmal Ch'en. A test trench across one lane, where it crosses a low area, disclosed the existence of stone paving. As such territory would be muddy in wet weather, the paving was presumably to provide dry footing for the traveler.

Special attention was given by Bullard to the main ceremonial center and the around that center at Mayapán. It is clear that property walls were not a part of the ceremonial architecture. It was further noted that, although there was a dense concentration of residential and residence-like buildings on the fringes of the ceremonial center, fewer walls occurred. These findings were in the main duplicated the smaller ceremonial group of Itzmal Ch'en. The suggestion is that the pattern of property walls and the function of apparently residential structures near ceremonial centers may have been different from that found elsewhere in the city.

The work of Ruppert and Smith, of Bullard, and of Proskouriakoff combined to show that a certain number of dwelling-type structures occur within the main ceremonial center. Some of these buildings are so placed as to indicate that they housed attendants and caretakers of the colonnaded halls and temples; others are so located as to suggest a late encroachment of this kind of structure into ceremonial areas.

Excavations by Bullard determined that in at least one instance a house and its property wall were built later than an adjacent colonnaded hall. One wonders if the building of residential structures in the ceremonial area was a consequence of the decline in importance of a public and priestly religion, with lessening use of the large temples, and the turn to private religious practices involving the worship of household idols.

Bullard also gave attention to problems of settlement pattern on the outskirts of Mayapán. He found that the concentration of dwellings fell sharply outside the city wall. East and west of the city houses occurred in some number for about 0.5 km beyond the wall; at the north and south they dropped off more quickly. Houses outside the city wall had the typical property wall pattern with yards no larger than those of dwellings inside the city, in spite of ample space. Exploration between Mayapán and the village of Telchaquillo, also an ancient site, revealed a pattern of dwelling remains that indicated Telchaquillo to have been a separate settlement.

Reconnaissance by Bullard at the sites of Uxmal, Kabah, and Sayil showed that property walls were not a feature of dwellings in the Puuc region. Evidence at Chichén Itzá was inconclusive.

As a basis for comparative architectural studies, a large-scale (1:200) plan of the main ceremonial center of Mayapán was undertaken by Proskouriakoff. Only half the area was surveyed this season, but some typical plans and assemblages already are evident. By and large the architecture, both in plans of buildings and in assemblage, more closely resembles the architecture of the East Coast than that of Chichén Itzá or other sites in Yucatán. Particularly numerous are colonnaded halls, buildings complete in themselves and unlike the so-called colonnades at Chichén Itzá. Also numerous are small single-room buildings at present called "shrines." Although temples occur at Mayapán in fair number, one again wonders if the emphasis on the "shrine" is not a step away from the presumably more elaborate ceremonies performed in the temples, and a move toward the private religious practices mentioned above in connection with dwellings. However this be interpreted, the number of shrines at Mayapán and in the east-coast sites indicates a cultural change of more than local significance.

So far we have little evidence bearing on the growth and development of the city plan. All constructions observed seem to belong to one cultural period and to represent a single technique of building. Numerous alterations of buildings, courts, and plazas suggest a considerable span of time and hold promise eventually of offering a sequence of changes in architectural style and construction practices. An earlier period, tentatively identified with the time of presumably late Puuc-style structures at Uxmal and Kabah, is represented by many re-used, dressed, and sculptured stones, but no continuity between these two phases has been established. The chronological relation between structures at Mayapán and those of the Toltec style at Chichén Itzá also remains in question. It is clear that building practices at Mayapán form a distinct complex, drawing on various sources. Certain features probably survive from the Classic period of Maya architecture; others mark the influence of Toltec culture. In general, similarities to the Toltec phase of Chichén Itzá architecture are less numerous than analogies with East Coast practices.

Major excavations were carried on by Shook, Strömsvik, and Adams, the last a graduate student in anthropology at the University of Chicago, working with this Department. Most of this work was done in the main ceremonial center at Mayapán. A systematic plan of operation calls for the thorough investigation of one or more examples of each seemingly important type of building. The character of many of the special-

ized units may be determined by this study and light be cast on their functions. Such excavation, moreover, frequently yields more than architectural data. Below the surface lie the bits of evidence that must be pieced together to obtain some small reflection of ancient life in Mayapán. This is a long, careful, and arduous process. Character, number, disposition, presence or absence of the imperishable, or relatively imperishable, remains of human activity are the data that must provide whatever we are to know of this bygone civilization.

Aside from the excavations of Ruppert and Smith in house mounds, the smaller exploratory operations of Bullard, Pollock, and Proskouriakoff, and the pottery trenching of R. E. Smith, sizable excavations involved 12 structures or building complexes, all but one in the main ceremonial center. It was satisfying, and somewhat surprising, to discover that we were dealing with a long sequence of building activity, although all construction apparently occurred within a single cultural period. The latter conclusion is of course tentative and yet to be tested. Aside from making a start in the definition of types of structures, and acquiring some information relative to the functions of buildings, we learned a good deal of burial practices so far as they pertain to the ceremonial center. Two shaft graves, several cists, and one simple, uncontained multiple burial were explored. The human remains found in each location varied from a single skeleton to literally dozens in one shaft grave. There is much to indicate that many, probably most, of these interments were of sacrificial victims. The implication is that human sacrifice was practiced on no small scale during this late period of Maya history, an inference confirmed by the early Spanish historians.

Grave furniture, or cache material, is disappointingly meager. Worthy of note because of its usefulness for dating, was the occurrence of metal, a tiny flake of gold and an even smaller fragment of copper from the shaft grave that yielded many human bones. Even pottery, however, found in abundance in surface deposits and in building debris, was scarce in association with burials.

One may speculate on the apparent poverty of the material belongings of the people. Judging from experience in other parts of the Maya area, one should expect to find the finest art objects of the culture in locations such as we have explored. It is of course possible that we have not looked in the right spots, that it is not in places of sacrifice but in the tombs of the rich and the exalted, of which we have little knowledge as yet, that the "treasures" will be found. There is also the matter of the cenote cult, the throwing of people and objects into cenotes, which some believe was flourishing at this time. No spectacular finds in cenotes have so far occurred Mayapán, but a wealth of material was

dredged many years ago from the Sacred Cenote at Chichén Itzá. As Chichén was reputedly a shrine center for all of Yucatán, it is possible that much of the wealth that went into sacrifice was directed there. These are possibilities to be considered, but one wonders if the evidence of human sacrifice on a large scale is not the important aspect of the problem. Had custom turned, at this late stage of Maya civilization, from the sacrifice of personal and ceremonial valuables to the sacrifice of human beings? In a waning and impoverished cult had human life, often in the form of slaves and captives, become cheaper than material belongings? Men held in bondage might frequently be foreigners and of different physical type, a fact sometimes determinable from skeletal remains. We hope that explorations will throw light on these questions.

Although the contract with the Government of Mexico under which we carry on our field researches does not require the restoration or solidification of excavated buildings and monuments beyond the point of assuring that they will suffer no further deterioration, it has been recognized that the interests of that government involve a certain amount of work of the sort that will leave on view to the public the results of archaeological researches. A limited program of solidification and restoration of buildings, designed to show representative examples of the architecture and methods of construction at Mayapán, has therefore been started. During the past season, two medium-sized structures, a temple and a shrine, and three lesser constructions were completed. This work was directed by Strömsvik.

The return of pottery, that supremely important indicator of change in time and culture, was on a considerably greater scale this season than had been anticipated. Well over 100,000 sherds were cleaned, labeled, and sorted. This work was under the care of Shook and R. E. Smith, the former handling material primarily from ceremonial constructions, the latter from cenotes, dumps, and refuse deposits. A characteristic of the pottery of the principal period of occupation of Mayapán is its simplicity, an exception being the effigy incense burners. This makes the task of detecting significant changes in the pottery, changes that indicate lapse of time and may indicate variation in custom, all the more difficult. It is nevertheless believed minor modifications of form and surface treatment of the dominant style of the time will submit to chronological ordering.

A few highly tentative conclusions from the study of the pottery are beginning to emerge. The apparent absence from dwelling-type structures of a kind of pottery (Black on Cream) associated with the apparent beginning of building activity in the ceremonial center suggests that the growth of the residential part of the

city followed the founding of the ceremonial center. Our excavations in house mounds are not sufficient to permit laying stress on the mere absence of a certain type of pottery, but future developments in this matter are worth watching. A finding that already seems firmly established is the late appearance, toward the end of the occupation of the city, of tremendous quantities of human-effigy incense burners. As might be expected, these incensarios are found in greatest concentration in connection with ceremonial buildings. Here would appear to be a new element in the local culture, a deep urge to appease the gods through the burning of copal, the native incense, in censers decorated with human figures applied to the exteriors.

The important trade ware (pottery imported from another area) at Mayapán is Fine Orange. Trade wares are often significant indicators of time-space relations. Most of the Fine Orange pottery at Mayapán seems to be of a late type associated with the principal period of occupation of the site, although rare examples of earlier types (X and Z) have been found. The history of Fine Orange, which is widespread in Middle America, is not well known. The littoral plains of Tabasco and Campeche have been thought by some to be the place of origin of the pottery. Heinrich Berlin, working with this Department under a Carnegie Institution Fellowship, has been carrying on archaeological reconnaissance in that territory. Preliminary indications are that this is indeed the home area of Fine Orange, a finding foreshadowed by Dr. Alberto Ruz Lhuillier's work in Campeche some years ago. Should the efforts of Berlin lead to the establishment of a sound stratigraphic sequence of defined types of this ware, it would be a boon not only to our researches in Yucatán, but to Middle American archaeology in general.

Berlin's reconnaissance included dozens of archaeological sites and traversed some of the most difficult country in Mexico. Highlights of his work are the beginnings of the definition of the home area of Fine Orange pottery; a start at charting the occurrence of the use of burned brick and mortar for building, a Maya custom apparently peculiar to the Tabasco area; the locating of a region that holds promise of yielding a full stratigraphic sequence, from Preclassic times to the conquest, of ceramics of the Tabasco plain; and the discovery at the ruins of Tortuguero of a fragment of a new monument bearing an Initial Series date (9.14.10.0.0?) in the Maya calendar.

In addition to her comparative architectural studies, referred to above, Proskouriakoff continued the recording and ordering for future study of the artifacts that have come from our excavations and from surface finds at Mayapán. Notable acquisitions this season were five arrowheads, rarely found elsewhere in Yucatán. Also of interest were several finely chipped,

large thin blades, and three knives or points, similar in form to the sacrificial knives of Chichén Itzá, found by Adams in association with human skeletons, two of the knives lying within the rib cases of the deceased individuals. Probably the most interesting piece in the Mayapán collection is a small head, or "mask," of dark igneous stone carved in Olmec style. Found by Ruppert and Smith in a house-mound excavation, the sculpture depicts in very simple form the typical features of an Olmec face. It is hard to judge whether this piece survives from the classic period of Olmec art or is a later imitation. Last may be mentioned a fragment of a shell ring or "collar," incised with hieroglyphs. Although the glyphs look Maya, they cannot be identified with any known characters, and they may conceivably represent a variant of Maya calligraphy or a system of writing yet unknown.

A long-overdue project of acquiring as complete a photographic record as practicable of the bas-relief sculpture of Chichén Itzá was carried out this season by DeHarport, a graduate student in anthropology at Harvard University, working with the Department. Although, the sculpture at Chichén is probably better known than that of any other site in Yucatán, many difficult subjects had never been photographed and some of the material was inadequately recorded. Approximately, 1,800 negatives were made and were developed in the field. It is thought that the record of this interesting and important body of sculpture is now virtually complete but for material that will be exposed by future excavation.

The hieroglyphic researches of J.E.S. Thompson are centered at present in the collecting of material for a catalogue of noncalendrical Maya hieroglyphs. An interesting aspect of this work is the promise it holds of shedding some light on unity or the local independence of centers in the southern Maya area and of assessing intercultural relations.

Hester, working under a Carnegie Institution Fellowship, has continued his studies of conditions bearing on the agriculture, economy, and population densities of the ancient Maya. Experiments were conducted in the clearing of Yucatán forest, without the aid of metal implements. Observations were made on the variety of cultivated plants, and soil samples were collected for analysis.

Roy has been engaged in compiling a historical geography of Yucatán as it was at the time of the Spanish conquest. This book will represent the fruits of many years' labor. Under the sponsorship of this Department, Pedro Carrasco, of the Department of Anthropology, University of Washington, made a trip to Mexico in order to survey the possibilities for research on the ethnohistory of the Yucatán Maya in pre-conquest and colonial times.

Shepard has given most of her time to the preparation of a book tentatively entitled *Ceramics for the Archaeologist*. Her laboratory work in ceramic technology has been divided between problems concerning the archaeology of Middle America and that of southwestern United States. As in the past, Shepard has aided archaeologists of other institutions as well as members of our staff.

A promising effort in the field of Yucatán ceramics has been a study of the occurrence of dolomitic limestone in pottery. Because of the extensive use by the lowland Maya of tempers from carbonate rock, it is important to follow in detail any characteristics that may differentiate such rock coming from different sources. A geological map covering the Maya area shows dolomite in the valley of the Usumacinta River and in southern Petén. It was one of the most distinctive varieties of carbonate rock found in the analysis of pottery from the well known sites of Uaxactún in northern Petén and San José in British Honduras, with implications that it was not of local origin. All Yucatán sherds for which microscopic examination had indicated the possibility of the presence of dolomite were tested. Although it was detected in relatively few sherds, most of them probably intrusive, ancient Yucatán sources of this rock cannot be ruled out, because dolomite was found to occur in certain local tempers collected several years ago by R. H. Thompson from modern pottery-making centers.

Thermal experiments made during the year included some basic work. Rate and temperature of oxidation of various types of gray and black wares were studied to test the possibilities of distinguishing effects of smudging, failure to oxidize carbon derived from carbonaceous matter in the clay, and reduction of ferric oxide. Tests have also been made of various types of clay to compare colors resulting from original oxidation and from oxidation following original reduction. The importance of these experiments lies in the fact that the color of sherds refired in air is used as a means of comparing pastes and judging the class of clay from which pottery was made. Results have shown that sintering and the reaction of iron oxide with constituents in the clay will cause irreversible color changes in some Yucatecan clays even within the ancient potter's temperature range. These studies are still in progress, and the control of firing atmosphere by the use of tank gas, now possible in Shepard's laboratory, gives promise of far more significant results than could be obtained before.

The Director, has been assisted in his administrative duties by Miss Lillian E. Lawrence, administrative secretary of the Department. Besides participating in the field activities of several members of the staff, the Director has given a large part of his time to the

review and preliminary editing of manuscripts from the staff. Final editing remains, as in the past, in the hands of Margaret W. Harrison. During the year a new series of papers, *Current Reports*, was inaugurated as a publication of the Department under the editorship of H.E.D. Pollock. The purpose of this series is to make available as promptly as possible the results of work in progress.

As was indicated in a preceding paragraph, the Department has taken into consideration the interests of the Mexican Government in the matter of the preservation of archaeological remains for public view. Early in the field season the Director opened this question with the Instituto Nacional de Antropología e Historia, the governmental organization under which we operate. It is pleasant to report that negotiations were conducted in a most cordial atmosphere and with a sincere desire for mutual understanding. The Instituto Nacional readily recognized our limitations in time and funds available for work of this sort. The result of these discussions was a program of solidification and restoration of buildings that is entirely practicable within the resources of the Department but at the same time will present a good range of examples of architecture and construction practices at Mayapán.

Early in February we were visited at our field headquarters near Mayapán by Dr. James B. Griffin, of the Museum of Anthropology, University of Michigan; Dr. Linton Satterthwaite, of the University Museum, University of Pennsylvania; and Dr. Gordon R. Willey, of the Peabody Museum, Harvard University. Bullard, a temporary member of our staff, journeyed with Dr. Willey at this time to British Honduras, where they spent several weeks in archaeological reconnaissance in the Cayo District, giving particular attention to the examination of house mounds. In June a number of the staff of the Department had the pleasure of conferring with Dr. Arnold J. Toynbee, of the Royal Institute of International Affairs and the University of London. Although the primary purpose of the conference was to supply Dr. Toynbee with current information relative to the pre-Columbian civilizations of America, problems were frequently approached from a somewhat different point of view from that usual to archaeologists, and the discussion was most stimulating to members of our staff. Dr. A. V. Kidder, retired Chairman of the Division of Historical Research, and Dr. Philip Phillips and Dr. Gordon R. Willey, both of the Peabody Museum, Harvard University, participated in this meeting.

In August 1952, the 30th International Congress of Americanists met at Cambridge, England. Thompson, who represented this Department at the meetings, was elected president of the Congress. During the year Pollock

was appointed Research Fellow in Middle American Archaeology, Peabody Museum, Harvard University.

I.43.
H.E.D. POLLOCK
<i>Department of Archaeology</i>
YB 53:263–267, 1954

Field work, which is principally the gathering of raw data, in archaeology is both a fascinating and a worrisome task. The removal of any shovelful of earth, the turning of a seemingly casual stone may lead one into work involving considerable time and effort, the significance of which can often be assessed only after the work is completed. The mass of material available to the excavator of any sizable archaeological site is so great that he cannot hope to handle all of it. He is constantly faced with decisions of what to exploit, what to by-pass; and he must weigh the whole effort at any site or in any region against other work in the larger area of his researches. Not only must he thus select with care the locations of his excavations, regretfully turning his back on situations that he would like to explore further or that hold tantalizing promise of worth-while results, but he also must look forward to the less exciting task of painstakingly labeling and recording the numerous small objects and the wealth of larger remains that emerge as the products of his digging. It is at this stage of his work that the archaeologist, half smothered under the weight of his accumulations, strives hard to see the forest from the trees and sometimes wonders if his methods are not open to improvement.

With these thoughts in mind it is heartening to be able to report that the results of the past field season, which involved sizable excavations at the large ruins of Mayapán, and survey combined with lesser digging elsewhere in the peninsula of Yucatán, have been most satisfying. Discoveries that first appeared as isolated phenomena are falling into place and forming a pattern that portrays interesting aspects of the life and times of the last important era of the prehistoric Maya, the subject of our present program of research. These findings range all the way from discoveries that throw light on the religious and aesthetic concepts of the people to the more conventional archaeological recon-

structions concerning the distribution of cultures and phases of culture in time and space.

Early in the course of our work at Mayapán it was realized that one of the outstanding opportunities offered at the site was a study of the remains of houses, for the most part presumably the dwellings of ordinary people, a side of Maya archaeology that had been sadly neglected. The surface survey and numbering of all structures within and adjacent to the great wall of the city has been completed. A. L. Smith and Ruppert report that a total of 4,140 buildings and platforms have been recorded. Approximately 2,100 of these appear quite surely to have served as homes, a figure that might well be increased were we able at this time to identify the function of certain questionable types of remains. Aside from the steadily accumulating information concerning burial, household religion, and the simpler sides of the culture of the time, some aspects of which have already been reported, the material provided by this survey, which will be amplified by additional excavation, offers the basis for the most accurate estimate of population that has yet been made of any ancient Maya city. It would be premature to mention any figure at this time, but the simple count of houses suggests that the settlement was large in terms of present day Yucatán.

The large-scale plan of the ceremonial center at Mayapán, a project begun last year to provide the basis for comparative architectural studies, was completed this season. In an area approximately 200 by 300 m there are no less than 114 structures varying in size from the great pyramid temple, the so-called Castillo, to small shrines, dwellings, and simple platforms. Proskouriakoff, who performed the mapping and has carried on preliminary studies of the architecture, notes that this is a far more crowded assemblage than is found at earlier ceremonial centers, and suggests that it came about, at least in part, from a decentralized ritual organization serving a multiplicity of cults.

As the mapping and architectural studies have progressed, there has been further definition of types of structures and of function. The dominant type of civic or religious building is the colonnaded hall. An interesting aspect of these buildings, which, because of their locations and certain internal features, have mostly been thought of as being for ceremonial use, is that some may have had a residential function. This is indicated by the close association of dwelling-type structures that seem to have been for the purpose of providing household services for the halls. Proskouriakoff raises the question whether the Mayapán hall is not, the counterpart of the ancient Mexican *telpuchcalli*, the bachelors' or men's house, or the *calmecac*, a monastery or place for the training of novi-

tiates, buildings that are described by the sixteenth century writer Sahagun as having existed at Tenochtitlán, the Aztec capital.

Major excavations, as in the previous field season, centered in and around the ceremonial, center at Mayapán. Although most of this work was directed toward the study of the civic and religious architecture, a phase of our explorations that is now virtually completed, some attention was given to the better class of residences, presumably the palaces or houses of the aristocracy. Fourteen temples, colonnaded halls, shrines, and platforms were explored by Shook; by Winters, a graduate student in anthropology at the University of Chicago, working with this Department; by P. E. Smith and Irving, graduate students in anthropology at Harvard University, also working with the Department; and by Pollock. Lesser excavations in ceremonial buildings were carried out by Proskouriakoff, Pollock, Strömsvik, and R. E. Smith. Proskouriakoff, Irving, and Thompson tested and explored several imposing residential groups and structures. Detailed accounts of this work will be found in succeeding sections of this report. A few of the more interesting discoveries and some of the broader implications of our findings will be mentioned here.

The finding by Winters of a group of effigy incense burners of pottery, badly broken but with most of the pieces present, enabled him to restore a number of those elaborate vessels. Although sherds of this type of censor are found in tremendous quantities, the pottery is so friable that a vessel normally disintegrates into hundreds of pieces; up to this year it had not been possible to restore a single example to anything approaching completeness. The censers, in which copal, the native incense, was burned, are typically large, some 40 or 50 cm high, with an anthropomorphic figure, modeled usually in the full round applied to the side of the vessel. The figures are of gods or of men impersonating gods. They are elaborately painted and show in detail attributes of the deities or symbols of office, ceremonial objects weapons, and accouterments of dress. Guided by the restored vessels, we should be able to identify fragments that previously were without meaning and to restore considerable sections of other censers. A study of the details of the figures offers promise in a subject that is otherwise scantily represented by archaeological remains.

Many of our excavations at Mayapán have produced fragments of wall plaster that show traces of painting. These occur with sufficient frequency to indicate that architectural decoration of this sort was common. It is rare, however, to find any sizable area of plaster still adhering to a wall, and no painted designs, other than those on fragments so small as to give little idea of the original, had been found prior to

this year. During the past season, Winters' excavations in a temple uncovered the wall of a room some 5 m long that retained fairly large areas of painting on the plastered surface. Most of the paint was on the lower half of the wall, only vestiges of the scene remaining on the upper part. As the mural had been covered by a later coat of plaster and much of the underlying plaster had pulled away from the wall, ready to crumble and fall at any moment, the removal of the surface layer and cleaning of the painting presented no small difficulty. This task was undertaken by Winters and a native assistant, and was carried on while the mural was being copied.

Under these difficult conditions, complicated by dust and sun, Proskouriakoff made a watercolor reproduction of the painting. The key to understanding the subject portrayed rested largely in deciphering, and relating to the rest of the mural, the fragmentary details on the upper part of the wall. Proskouriakoff's solution of the problem and restoration of the composition were brilliantly successful. The scene depicts five buildings, possibly temples, resting on a low platform. The walls of the buildings and platform are elaborately decorated with painted designs. The architectural style suggests a mixture of Maya and Mexican traditions and is of a sort not suspected from the remains of buildings at Mayapán or elsewhere in Yucatán.

In our last annual report [Chapter 1.42] it was noted that the late stage of Maya history represented by the principal remains in Mayapán seemed to have witnessed some rather profound changes in general cultural level and in religious structure as compared with the old classic Maya civilization. Aside from the obviously inferior art and architecture, this change was expressed in the poverty of ceremonial offerings. The numerous shrines, apparently a late development, suggested the decline in importance of a centralized religious organization and the growth of a multiplicity of cults. This process of decentralization may have attained its ultimate expression in the transference of much of what remained of religious ceremonialism to the private dwelling.

Our excavations and explorations this season in the finer residences are revealing in respect to these matters. The shrine room in the house or the separate shrine in the courtyard before the house appears to be customary, if we may judge by the examples so far explored. More surprising is the fact that both in excellence of building and in quality and variety of ceremonial objects the important houses thus far tested have proved richer than the temples and other ceremonial structures. One is tempted to picture a time when the gods were slighted in favor of personal comfort and glory. More evidence is needed, but in an era of deca-

dence, which is clearly indicated by inferior art forms and the falling-off of craftsmanship as compared with earlier times, it is not surprising to find cultural decay and materialism walking hand in hand.

In the native literature and early Spanish accounts that deal with the preconquest history of Yucatán there are numerous references to the fall of Mayapán, the last great city of the Maya. This event, which presumably occurred about A.D. 1450, is variously referred to as the "abandonment," "depopulation," or "destruction" of the town, and is often associated with fighting of the nature of civil war. Our excavations in 1953 uncovered several instances of the apparent looting of altar deposits, and it seemed clear that this had been done in ancient times, before the buildings that housed the altars had collapsed. Although these findings suggested insurrection or invasion and pillage, that interpretation was by no means certain. The gradual abandonment of the city from causes other than strife, and the breakdown of old social and religious forms, might in time leave the empty temples as open to acts of vandalism as the more cataclysmic effects of war.

Discoveries of the past season, have thrown light on the nature of the abandonment of Mayapán. Not only have we uncovered several more examples of the robbing of altars prior to the collapse of buildings, but we have noted three instances of charred timbers beneath the debris covering the floors of structures. These charred timbers are unquestionably the remains of roof beams. As it would be relatively difficult to set fire to the wooden supports in a beam and mortar roof, owing to the nature of the construction, there is good evidence that the buildings were purposely burned. There is also evidence from the pottery on the floors that this occurred late in the occupation of the city and that, in at, least one instance, the building was in use at the time of destruction. These findings clearly suggest that the sack and destruction of the city by hostile forces, as implied by old records, did in fact take place.

In our annual report of two years ago [Chapter 1.41] we discussed a number of problems dealing with the history of Yucatán during the five centuries preceding the Spanish Conquest. The gist of those remarks was that a reappraisal of the archaeological evidence might lead one to question prevalent reconstructions of the history of that period. The work of Ruppert, Shook, A. L. Smith, and R. E. Smith at Chichén Itzá this season has provided additional information bearing on these questions. The survey of house mounds there discloses no dwellings like those at Mayapán; the collections of stratigraphic samples of pottery show a very small proportion of types assignable to the Mayapán Period. This leads the investigators to suggest that the permanent occupation of Chichén Itzá terminated at or near the end of the Toltec Period at that city, other-

wise known as the Period of Foreign Domination. They further suggest that the small amount of ceramic remains of the Mayapán Period, or Period of Maya Resurgence, represents no more than the leavings of pilgrims who journeyed to their holy well, the Sacred Cenote, to make sacrifice. This, in the main, is confirmation of one of the standard reconstructions of Yucatán history.

Whatever the final answer to these questions, and the evidence is not yet conclusive, a matter of equal importance is that the ceramics of Chichén Itzá and Mayapán strongly indicate that the major break or change in cultural tradition occurs not at the beginning of, or during, the Period of Foreign Domination, but at the close of that period and with the ascendancy of Mayapán. This revives questions raised earlier as to the character of the later period and the correctness of our designation of those times as the Period of Maya Resurgence, questions discussed in the annual report referred to above.

The foregoing paragraphs have touched on some of the wider implications of our findings of the past season. Detailed reports on this work will be found in succeeding sections. There also will be found reports on explorations in the vicinity of Mayapán and on solidification of buildings at Mayapán by Strömsvik, on the ceramic stratigraphy of Mayapán and its vicinity by R. E. Smith, on the art and artifacts of Mayapán by Proskouriakoff, on explorations in Quintana Roo by Strömsvik, Pollock, and Berlin, on archaeological reconnaissance along the east coast of Yucatán by William T. Sanders, and in Tabasco and Campeche, by Heinrich Berlin, Carnegie Institution Fellows with this Department, on research in ceramic technology by Shepard, and on field studies of Maya agriculture by Joseph A. Hester, Jr., also a Carnegie Institution Fellow with this Department.

1.44.

H.E.D. POLLOCK

Department of Archaeology

YB 54:265–269, 1955

The year covered by this report saw the completion of a program of field activities initiated in 1951. As is known from previous reports, these activities have been concerned with the peninsula of Yucatán. Major exca-

vations have been carried out in the large pre-Columbian city of Mayapán, and archaeological surveys combined with lesser excavations have been advanced in a number of other locations and areas within the peninsula, notably along the East Coast and in the Tabasco-Campeche region. This phase of our program is ended. There remains the task of studying the large collections of objects and the mass of data that are the products of this work.

It may be of some interest to those who have never been immediately in touch with archaeological field work to have some idea of the size of an operation such as ours that has extended over several years. Approximately half a million pieces of pottery, varying in condition and size from whole jars to scraps no bigger than one's fingernail, have emerged from the digging. Each single piece has passed through the hands of at least one person and usually of several people. By far the greater part of this material is classified and recorded; even the fragments so weathered as to elude classification are counted and a record is made of their provenience and association with other pottery and materials. Lesser artifacts, tools, ornaments, and the like, of stone, bone, antler, shell, coral, metal, pottery, stucco, even fragments of textile, have been catalogued to the number of 1,400 specimens. Nor does this give a complete picture of the amount of such materials, for several objects are sometimes grouped under a single specimen number, and the cataloguing is not yet complete. Brief description, measurement, a rough sketch are the minimum of data that go with each specimen. Skeletal remains, human and animal, the former to be measured and studied, the latter to be identified, are to be numbered by the boxful. Stone sculptures, architectural and monumental, are recorded by the hundred. This list is by no means complete, for example, there are page upon page of architectural drawings, but it suggests the amount of material that is dealt with. These are the products of excavation. With their appearance above ground and their initial recording, the task of the archaeologist is only fairly begun.

In the course of our several field seasons at the large ruins of Mayapán, our work has proceeded along two main avenues of approach, namely, surface survey and excavations of varying magnitude at selected locations. Because of the great number of building remains within the city wall, only a small fraction of which we could hope to excavate within the time allotted to our program at this site, survey work took on particular significance, a significance amplified by our interest in the simple dwellings that make up so large a proportion of the remains. It was not, then, until the end of the 1954 season that our program of surface examination stood virtually completed. This situation

allowed us to devote almost complete attention to excavation during the 1955 season. It further allowed us to judge what lacunae existed in our work up to that point, and where we might most profitably direct our efforts during our last season at Mayapán.

As can well be imagined, there were numerous situations that seemed to merit further investigation, and there were a number of problems the solutions of which held promise of providing worthwhile knowledge. It appeared quite clear, however, that our work should give primary attention to two classes of remains. We needed a better sample of excavated house mounds than we had been able to obtain up to that time, showing the various types of structure and their distribution within the city. We also wished more knowledge of a class of buildings that at first had been thought to be civic or religious in function, but which further knowledge had given good reason to believe were the residences of the aristocracy or nobility. Most of our effort was kept within these two areas during the past season.

Ruppert and A. L. Smith, who carried the chief burden of surface survey at Mayapán, undertook widespread excavations in simple house mounds. They also worked in some of the larger structures of the second class mentioned above. The data they have accumulated must of course undergo careful study before they are interpreted. A factual statement of their findings appears in a following section of this report. One of the most promising aspects of their work was the complete excavation of several house groups. It is hoped that excavations of this sort will lead to some understanding of the pattern of residence in the extended family and will throw some light on the organization of domestic life within the group. As it seems quite clear that household worship was an important part of Maya culture at this time, there is also the question of how religion functioned within the family group.

One of the most imposing assemblages of buildings at Mayapán is the large, quadrangle partly excavated this season by Proskouriakoff and Temple, the latter a graduate student in anthropology at Yale University who worked with this Department during the field season. This quadrangle, which encloses a sizable courtyard, seems clearly to have been residential and very probably merits the often misused term "palace." The group is too large to have allowed complete excavation, but sufficient exploration was carried on to gain an excellent idea of the growth and development of the complex. There is good reason to believe that it was planned from the beginning to be a residence. Although there was continual tearing down, rebuilding, renovation, and general change of plan, it is surprising to discover that the complex was begun at a late date in relation to the main ceremonial center

of the city. This relative lateness appears to characterize many of the residences we have tested, and this fact raises some interesting problems in regard to the growth of the city. Like many other structures, the quadrangle seems to have been occupied at the time of the violent destruction of Mayapán, for many objects, apparently left by the departing inhabitants, were found on the floors of rooms beneath debris from the burned roofs. An interesting discovery was a kitchen that retained a number of its furnishings, with other household articles and a deep deposit of midden refuse off the slopes of the terrace outside the room. It was not until this season that any kitchen had been identified. The removal of valuables, as witnessed by the looting of caches, was prevalent in the quadrangle as in many other buildings we have excavated, but a new light on the behavior of a presumably fleeing group of people was provided here through the discovery of a tremendous number of effigy incense burners dumped into a plundered tomb, as though the household gods had better be broken and buried than allowed to fall into the hands of people of alien beliefs. It is possible that the breaking occurred at the hands of the alien group, but there are indications that it was done by the departing residents of the palace.

A residential group almost as imposing as that referred to above was excavated by J.E.S. Thompson and D. E. Thompson, the latter a graduate student in anthropology at Harvard University, working with this Department. A discovery of particular interest was a cremation, sealed within a pottery jar, buried in the altar of what appeared to be the family oratory. As is pointed out by Thompson and Thompson in a succeeding section of this report, this cremation strongly suggests a cult of ancestor worship such as that described by Bishop Landa.

Although our excavations this past season were primarily directed toward gaining knowledge of the domestic side of Maya life, additional work of this sort being carried on by Chowning, a graduate student in anthropology at the University of Pennsylvania, temporarily with this Department, and by D. E. Thompson, some effort was also directed toward amplifying our knowledge of the civic and religious aspects of the culture. Pollock undertook limited excavations at a relatively large group of buildings that from surface examination suggested functions involving ceremonialism but that were sufficiently aberrant from known types to leave considerable doubt. It appeared after excavation that this group had almost certainly had people resident there at certain times, possibly, preparatory to religious rites and ceremonies, possibly for religious training, but that there was little reason to think the structures were houses in the sense of a family residence. Shook and Chowning excavated round

buildings that in each case can almost surely be identified as temples. Strömsvik, Chowning, and D. E. Thompson carried on limited excavations at the small ceremonial center next Cenote Itzmal Ch'en in the eastern part of the city. This group was later mapped by Proskouriakoff.

As reported previously, the Department has cooperated, through informal agreement, with the Instituto Nacional de Antropología e Historia of the Mexican Government in carrying out a limited program of repair and consolidation of selected structures at Mayapán. The effort has been to leave on display one example of each of the major types of building at the site. Strömsvik has had charge of this work. During the past season the program of repair was completed with the consolidation of a round temple, of a typical section of the city wall, and of one of the major entrances in the wall. It is believed that future visitors to Mayapán will be able to gain a good idea of the range and character of the architecture there.

During the past season a start was made on the more general studies leading to interpretation of the large amounts of raw data that have been amassed from four seasons of field work. So far these studies have been confined to pottery, work that has rested in the hands of Shook and R. E. Smith. The former devoted the major portion of his time to analyzing the large collections that have accrued from our digging in the main ceremonial center at Mayapán. Because of the wealth of ceramic material recovered during the current season, which was handled by Smith, the latter was able to give less time to such detailed studies. He did, however, prepare a preliminary report, now in press, on the early, pre-Mayapán Period pottery from Mayapán and its vicinity.

As noted earlier in this report, the Department has carried on a program of archaeological reconnaissance in other regions of the Yucatán peninsula than the Mayapán area. During the past season Sanders, working with the Department under a Carnegie Institution fellowship, continued his ceramic survey of the East Coast. His work of the previous year had resulted in exploration of the northeastern tip of the peninsula as far south as the ruins of Tulúm and including the island of Cozumel [Chapter 33.2]. Knowledge gained from this exploration and ceramic testing allowed him to select two important sites, Tulúm and Tanchah, for intensive work this year in his search for stratigraphic sequences of ceramic remains. Late in the season reconnaissance was extended southward to the Chetumal Bay area, where testing was carried out at the sites of Ichpaatún and Calderitas. With the collections now in hand it is confidently expected we can provide a far sounder basis than previously existed for the understanding of cultural sequences along the East Coast

and of the relations of that area with other parts of the peninsula. It is already apparent from a preliminary study of the pottery, not only that many of the East Coast sites are of the same general period of time as Mayapán, a fact that had long been suspected, but that the two areas were unquestionably in contact. It is not unlikely, moreover, that the East Coast remains, because of the sequent stages of culture there, can give us more information on the sources and development of late Maya civilization than the more renowned, but relatively short-lived, capital city of Mayapán.

Archaeological reconnaissance was carried on by Shook in the environs of Mérida along the coast of Campeche, and in the Chiapas highlands. This work was particularly important in calling attention to the wealth of Preclassic remains, both ceramic and architectural, in one small area of northern Yucatán; in noting on the west coast of the Yucatán peninsula the existence of remains apparently of the Toltec-Chichén Itzá type and period, remains that are extremely scarce in Yucatán outside the type site; and in discovering a magnificent stratified deposit of Preclassic materials in the archaeologically little known upper drainage of the Grijalva River.

Berlin, whose Carnegie Institution fellowship ended during the period covered by this report, devoted his time to the study of, and preparation of a report covering, the archaeological material recovered by him during the two previous field seasons in Tabasco and Campeche. Of special interest was the isolation of a late type of Fine Orange pottery found abundantly along the southeastern shore of the Gulf of Campeche. This same pottery has been encountered in small amounts at Mayapán, thus establishing a chronological and cultural link between that city and the southwest sections of the peninsula. Berlin also visited several small Maya sites where interesting and previously unknown sculptures were recorded.

Beside seeing her forthcoming monograph, *Ceramics for the Archaeologist*, through the press, Shepard has continued her laboratory research in ceramic technology. Several lots of sherds from Mayapán have been examined for evidence of changes in paste composition that might be useful diagnostics for subdividing the period represented, for intrusive sherds that would illuminate foreign contacts, and to evaluate the position of this pottery in the technological history of Yucatán ceramics. Work has also been done on the analysis of Fine Orange pastes preparatory to a study dealing with that important ware. Basic research concerned with the thermal behavior of clay minerals has continued, notably by means of thin sections of polished clay slips which have uniform orientation, facilitating the determination of optical properties. Shepard is also engaged in a review of literature on

contemporary pottery making in preparation for a systematic analysis of pottery-making traits with respect to their degree of dependence on environmental conditions, and in order to judge the feasibility of identifying forming techniques of prehistoric pottery by means of the orientation that clay particles are given by the forces applied in building.

Toward the close of the field season Dr. Eduardo Noguera, Director of the Dirección de Monumentos Prehispánicos, Instituto Nacional de Antropología e Historia of the Mexican Government, and Dr. Alberto Ruz L., Head of the Oficina de Monumentos Prehispánicos en Yucatán, visited Mayapán and our Mérida laboratories at the invitation of the Department. Dr. Noguera and Dr. Ruz inspected our operations at the ruins, giving particular attention to our work of consolidation of buildings and to our procedures for protecting monuments from deterioration following excavation. At this time we were able to discuss procedures for transferring guardianship of the archaeological zone of Mayapán to the Mexican Government. This act was accomplished in May 1955, when an official guardian, a native of the village of Telchaquillo, was appointed by the Government.

On July 1, 1955, Earl H. Morris retired, thus terminating 31 years of service with the Institution. Morris' first work with the Department was in Middle America, where the Institution was just beginning its large program of excavation and restoration at the ruins of Chichén Itzá in Yucatán. It later developed, however, that his true interest lay in the archaeology of the Southwest of the United States, an area in which he had worked for some years prior to joining the staff of this Department. After a few seasons in Yucatán he consequently transferred his operations to the Southwest, where the Institution was willing to undertake a small program, and, with the exception of a single season in Guatemala, his work has continued in the area of his original interest. So successful have been his researches and so outstanding his contributions that in 1953 he was presented the Alfred Vincent Kidder Award of the American Anthropological Association.

On July 1, 1955, Margaret W. Harrison resigned as Editor of the Department of Archaeology, ending an association of 21 years with the Institution.

As a tribute of recognition of his outstanding achievement in archaeology, the Government of Guatemala has conferred on Alfred Vincent Kidder, past Chairman of the Division of Historical Research, the decoration of the Order of the Quetzal, in the grade of Knight Commander.

1.45.

H.E.D. POLLOCK

Department of Archaeology

YB 55: 335–338, 1956

In last year's annual report [Chapter 1.44 this volume] we noted the completion of a program of field activities concerned with the peninsula of Yucatán. The past year has seen the staff engaged in the preparation of preliminary reports covering the work of the 1955 field season and the beginning of the larger, definitive studies that will follow.

The handling of archaeological collections and recorded data is, naturally, determined by the nature of the materials. Buildings cannot be collected, nor can excavations be left open indefinitely without undue risk of deterioration of the exposed remains. Architecture must, then, be recorded in such detail that all pertinent data will be available after the worker has left the site of his excavations. The same is true, also, of large sculptures and monuments. Pottery is transportable, but it frequently occurs in such amounts that only preliminary sorting and classification can be done on the spot. Final study, when the full range of material is at hand, must await a later time. Other artifacts, covering a large range of relatively imperishable materials, also may occur in considerable numbers. In the busy press of an active field season these objects can receive only preliminary cataloguing, and they too, like the pottery, must be set aside for later, more painstaking study.

The problems of handling collections and data indicated in the preceding paragraph have been met in a variety of ways. Those members of the staff concerned with architecture, and with the wider implications of building remains, such as population estimates, settlement patterns, and the life and customs of the people in general have been at work in Cambridge. Over the years of active field work our collections of pottery and other artifacts have steadily moved from the site of excavation to a central repository in Mérida, where they were systematically stored. To study these collections, certain members of the staff traveled to Yucatán this past winter. Human skeletal remains, many extremely fragile, were stored at our field camp, and the study of this material by a physical anthropologist also required his going to Yucatán. Lastly, we should mention collections that could be shipped to the United States for study by scholars in fields other than archaeology. These materials included animal bones, selected specimens of shell and stone, fragments of textiles, and all artifacts of metal.

In July 1955, Edward I. Fry, a graduate student in anthropology at Harvard University, spent several weeks at the Department's field camp in Telchaquillo, Yucatán, studying our collections of human skeletal remains. Because of the nature of the material he concentrated his attention on evidences of pathology, anomalies, and deformation exhibited by the remains rather than attempting to accumulate extensive amounts of anthropometric data. Fry's report on his findings is now in press. Highlights include comparative data on types of tooth filing, the low incidence of carious teeth and of healed fractures of long bones, and the high incidence of antero-posterior cranial flattening and of degenerative arthritis.

R. E. Smith and Proskouriakoff went to Mérida in December 1955, the former to work with our pottery collections, the latter to study our other collections of artifacts. Proskouriakoff returned to Cambridge early in March, and is now engaged in preparing a definitive report on her work. Smith, faced with a very large amount of material, remained in Yucatán until the end of May.

A minor exception to the ending of field activities in 1955 was the collecting of pottery samples at the ruins of Uxmal and Kabah during the past winter. These small excavations, which were carried out by Strömsvik during February, were designed to provide R. E. Smith with background material for his studies of Mayapán ceramics. The results of the work are reported by him. As our 5-year contract with the Mexican Government had expired in September 1955, Strömsvik's excavations were made under special permission from the Instituto Nacional de Antropología e Historia, and in co-operation with its work at those sites.

It has been mentioned above that studies of parts of our collections have been undertaken by scholars in fields other than archaeology. These studies are listed by Proskouriakoff in a subsequent section. Particularly worthy of note are the spectroscopic analyses of metal objects, some of which will be subjected to further tests, by Dr. W. C. Root, of Bowdoin College, and the identification of large collections of animal bones by Mr. Clayton Ray, a graduate student at the Museum of Comparative Zoology of Harvard University. Although the work on the metals has not progressed sufficiently for any details of the findings to be given, this study holds promise of indicating routes and sources of trade and commerce; no metal being native to the Yucatán peninsula, all objects of this material must have been imported.

In the matter of the identification of animal bones produced by our excavations, the Department was most fortunate in obtaining the assistance of Ray, who has made over 6,000 identifications of mammals, reptiles, amphibia, fish, and birds. It is pleasant to relate that, aside from the anthropological information to be

derived from these identifications, such as the dietary habits of the ancient Maya and the domestication of animals by these people, studies yet to be made, our collections were of sufficient interest to another discipline to merit the preparation by Ray of two papers to be published in zoological journals.

While referring to assistance from other disciplines, we wish to report the dating by the carbon-14 method of two charcoal samples from Mayapán. The age determinations were made in 1955 by Professor Hessel de Vries, of the Physical Laboratory, State University of Groningen, Holland. The specimens were selected in the hope of marking, as nearly as possible, the beginning and ending of the principal period of occupation of the city. The precise provenience and other details relative to the samples will be given in a report now under preparation. Suffice it to say here that the earlier specimen (GRO 452) yielded a reading of 700 (A.D. 1255) ± 95 years. This finding is in close accord with the date expected on archaeological grounds. The later specimen (GRO 450) yielded a reading of 335 (A.D. 1620) ± 90 years, approximately 200 years later than the expected date and falling in post-Columbian times.

During the past year Ruppert and A. L. Smith have been occupied primarily with the preparation of preliminary reports covering their extensive excavations in dwelling remains in Mayapán and their reconnaissance and excavation of similar remains elsewhere in Yucatán. One such report is now in press. They have also begun the analysis of the large amounts of data accumulated during five seasons of field operations at Mayapán and other ruins, an analysis that should materially increase our knowledge of the character of domestic architecture, patterns of settlement, and sizes of populations in Mayapán and vicinity.

Thompson, in addition to preparing a report on his excavations at Mayapán in 1955, has continued work on his catalogue of Maya hieroglyphs [Chapter 6.11]. The end of this long and arduous undertaking is now in sight.

During the latter half of the period under review Shook was on leave of absence from the Institution. This leave was to enable him to lead an expedition of the University Museum, University of Pennsylvania, to the great lowland Maya ruins of Tikal in Guatemala. Before his departure he was engaged in preparing reports covering his activities in Yucatán during the 1955 field season.

Sanders, whose fellowship with the Institution ended January 1, 1956, has been occupied with the preparation of a report on his archaeological survey of the east coast of Yucatán, a survey that extended over two field seasons. His report is expected in the near future.

Shepard has been pursuing studies in geology and mineralogy to broaden her background in those subjects. This work has included a research project on clay mineralogy in which she is applying X-ray and petrographic methods to the study of the thermal behavior of clays within the temperature range of primitive firing. Her survey of technical methods in archaeology has been supplemented by abstracting for *Studies In Conservation*, International Institute for the Conservation of Museum Objects; she is serving on R. J. Gettens' American working team. Shepard has also prepared sets of models demonstrating the factors affecting the color of fired clay for the purpose of clarifying basic principles of ceramics for archaeological students.

The foregoing covers the research activities of the staff. There are some administrative matters which should be reported. Most important is the decision of the Institution to discontinue its archaeological activities some two years hence.

Our 5-year contract with the Mexican Government, under which our program of field activities in that country had been carried out, expired in September 1955. As excavations were at an end, and the terms of the contract allowed a period of two years following the completion of the work before our collections need be turned over to the Instituto Nacional de Antropología e Historia, renewal of the contract was not requested.

By late winter 1956 it was apparent that our field camp at Telchaquillo was no longer needed. During March and April all equipment at the camp was moved to Mérida, and the property, which we held on lease, was returned to the owner. This operation was carried out by Strömsvik.

Before the closing of the Telchaquillo camp, it had been decided by the Institution that the greater part of the field equipment no longer needed by the Department should be turned over to the Instituto Nacional de Antropología e Historia, to be used in its archaeological researches in the Maya region. This policy, which assured that the equipment would continue in the uses for which it originally was purchased, has resulted in the handing over of considerable amounts of highly useful equipment to the Yucatán office of the Instituto Nacional.

Toward the end of April the President of the Institution and the Director of the Department made a journey of approximately a week's duration to Yucatán, Guatemala, and Honduras, in order to review some of the past activities of the Institution in the field of Middle American Archaeology. The ruins of Uxmal, Kabah, Chichén Itzá, and Mayapán were visited in Yucatán, where the President and the Director were joined by R. E. Smith and Strömsvik. In Guatemala the great ruins of Tikal, the largest known Maya city, were inspected with the aid of Shook, who was just completing his

field season were under the auspices of the University Museum of the University of Pennsylvania. The following day, again in the company of Shook the ruins of Copán in Honduras were visited. Lastly, the fine Museo Nacional de Arqueología y Etnología de Guatemala, in the organization of collections and the installation of exhibits for which the Institution had played a prominent role, was inspected.

The fifty-fourth annual meeting of the American Anthropological Association held in Boston during November 1955, included a symposium on Middle American anthropology and thus was of particular interest to our staff. Papers were presented by Proskouriakoff and Thompson; Shook acted as discussant of a paper; other papers were given by a number of people who at one time or another have been associated with the Department.

During the past year Proskouriakoff has been appointed Assistant Editor (Middle America) of *American Antiquity*, replacing Thompson.

It is with deepest regret that we report the death on June 24, 1956, of Earl Halstead Morris, a recently retired member of the staff of the Department. His outstanding accomplishments in the fields of Southwestern and Middle American archaeology were described [Chapter 1.44] at the time of his retirement. American archaeology has suffered a grave loss with his death.

In recognition of extensive research work and brilliant publication, J. Eric S. Thompson was awarded the Viking Medal in archaeology for 1955. Thompson is the second member of the staff of the Department to receive this award since its inception 10 years ago. The first recipient of the medal was Alfred Vincent Kidder, then Chairman of the Division of Historical Research.

It is a pleasure to be able to record yet another honor for our past Chairman. In October 1955, Dr. Kidder received from the University of San Carlos, Guatemala, the degree of *Doctorado honoris causa*.

H.E.D. POLLOCK

Department of Archaeology

YB 56:407-410, 1957

The work of the year under review has followed the pattern indicated in our previous annual report [Chap-

ter 1.45 this volume]. With the completion of field activities, the efforts of the staff have been directed to the production of preliminary reports on the field work and to the broader studies that will lead to definitive statements covering the results of our recent program of researches in Yucatán.

Our progress in the first area is recorded here in a subsequent section dealing with publications. This phase of the work is now virtually completed, only two or three such reports remaining to be published.

In connection with the larger studies R. E. Smith worked in Yucatán, from the beginning of December 1956 until the end of May, with the large collections of pottery stored in our Mérida headquarters. Because of the vast amount of material of this nature that was produced in our five seasons of excavations at Mayapán and elsewhere in the Yucatán peninsula, this study is the most time-consuming of the several major divisions of our researches. A statement of Smith's progress is contained in the following section of this report.

Thompson made a trip to Yucatán in March 1957 for study of the effigy incense burners recovered from Mayapán, to determine what light they would throw on the religion of Mayapán and of the late preconquest Yucatecan Maya in general. The results of this work were highly rewarding, in that he was able not only to identify a number of the gods or personages represented on the incense burners and to make tentative identification of others, but also to show how considerably the religion of Mayapán was influenced by foreign ideologies. A more detailed report on this work will be found below.

A. L. Smith has continued his research dealing with the domestic architecture and living patterns of the people of Mayapán. The raw data for this study are extensive, and their ordering and analysis are of necessity a slow, painstaking process. The work has progressed from the study of types of individual structures to the examination of groups of buildings that presumably housed family units. It is too early as yet to anticipate the results of these studies.

Proskouriakoff has been engaged in preparing reports on the formal architecture of Mayapán and the artifact remains, other than pottery, from that site. In regard to architecture, her careful work has developed some interesting information concerning assemblages of specific types of structures that may have functioned as ceremonial units. It has also brought out the necessity for changing our ideas in regard to the type, and presumably the function, of certain buildings. A highlight of the study of artifacts is the suggestion that the date of the introduction of metal into Yucatán may have been later than it has commonly been thought to be.

During the past year Shook has been on leave of absence from the Institution. As was stated in our last report, he has been in charge of the work of the University Museum, University of Pennsylvania, at the ruins of Tikal in Guatemala.

Shepard has continued her academic work in geology in anticipation of making that her principal field. Certain of her studies, especially theoretical igneous petrology, metamorphic petrology, ore genesis, paragenesis, and clay mineralogy, have been of direct benefit in her research in ceramic technology.

In addition to her class work and a review of the literature of clay mineralogy, Shepard has investigated Maya pigments, particularly Maya blue, an exceptional pigment that has so far defied identification. In collaboration with Dr. R. J. Gettens, of the Freer Museum, Smithsonian Institution, Shepard has examined petrographically a number of blue minerals obtained from the U. S. National Museum through Dr. Gettens. She has also run thermal tests and made some experiments in synthesis. She has now arranged for a micro-organic analysis, the results of which, together with results of a semi-quantitative spectrographic analysis being supplied Dr. Gettens by the U. S. Geological Survey, should define the composition of the pigment.

During February and March 1957, the Director had the opportunity to accompany Dr. Gordon R. Willey and Dr. Philip Phillips, of the Peabody Museum, Harvard University, on a visit to certain ruins, museums, and private collections in Mexico. The journey extended from the northern border of the country to Yucatán, most of the distance being traversed by automobile. Quite aside from the archaeological remains, a large part of which were seen for the first time by the Director, he was reminded of the value of first-hand knowledge of the environment in which the various aboriginal cultures existed. The trip was a most stimulating experience.

As has been mentioned in earlier reports, the Department has frequently relied upon the aid of scholars in fields other than archaeology. Shepard's collaboration with Dr. R. J. Gettens on Maya pigments, has been referred to above. The work of Dr. W. C. Root on the analyses of metals recovered from Mayapán, noted in last year's annual report, has continued. We are indebted to Professor Hessel de Vries, of the Natuurkundig Laboratorium der Rijks-Universiteit te Gröningen, Holland, for another Carbon 14 age determination of charcoal from Mayapán. The specimen was selected because of its important archaeological associations. It marks a late phase in the history of Mayapán. The sample, GRO 1166, gave a reading of 400 (1557 AD $\pm$ 55 years). Allowing a value of 100 to 200 years for "Suess effect" brings the date closely in line with historical evidence that Mayapán was abandoned

about 1450 AD.¹ Lastly, the Department has been instrumental in obtaining for Professor W. Sandermann, of the Institut für Holz- und Zellstoffchemie, Reinbeck bei Hamburg, Germany, samples of contemporary tropical woods to use in connection with his identifications of ancient woods from Maya ruins.

In anticipation of the closing of this Department a year hence, we have continue to dispose of certain records and equipment no longer needed. Gifts of this sort have been made to the Museo Nacional de Arqueología y Etnología of Guatemala, the Instituto Nacional de Antropología e Historia of Mexico, the University Museum of the University of Pennsylvania, the University of Arizona, the University of Colorado, and the Haddon Library of Cambridge University, England.

In October 1956 the Director attended an international conference on radiocarbon dating at Andover, Massachusetts sponsored by the R. S. Peabody Foundation and the National Science Foundation. During the same month the Director anticipated in the first meeting of the Committee for Latin American Anthropology of the National Research Council, held at the Wenner-Gren Foundation, New York. The purpose of the meeting was to discuss plans for the preparation and publication of a handbook of Middle American Indians. In February 1957, Dr. Gordon Willey, Chairman of the above committee, and Pollock met with a number of Mexican colleagues at the Museo Nacional de Antropología in Mexico City for further discussion of the same subject.

Karl Ruppert, the senior member of the staff in length of service, retired on October 1, 1956. His retirement terminated an association of almost 32 years. Coming to the Institution early in 1925, Ruppert did his first work under the late E. H. Morris in his excavation and restoration of the Temple of the Warriors at Chichén Itzá. Ruppert's talent for the complicated procedures involved in creating authentic restoration of the intricate stone architecture of the Maya soon became apparent, and most of his time for the next dozen years was devoted to work of this sort. At Chichén Itzá the Temple of the Wall Panels, the Caracol, the Mercado, and the Sweat House stand as monuments to his talent.

Although mainly occupied in these early years with architectural restoration, Ruppert had already embarked upon some of the explorations that were to characterize the next phase of his career in Middle American archaeology. By 1936, when the rebuilding of the Sweat House at Chichén Itzá was completed, he had traveled overland to the east coast of the Yucatán peninsula, to the ruins of Yaxchilán on the Usumacinta River, and had made three trips into the virtually unexplored regions of southeastern Campeche and

southwestern Quintana Roo. In the next six years his travels took him to southern Veracruz, where he worked in co-operation with archaeologists of the Mexican government, to southern Chiapas, again into Campeche, and as far as Nicaragua. After the interruption of the war years, which brought overseas service, Ruppert was soon again embarked upon difficult explorations, now to eastern Chiapas and once more to Campeche.

With the beginning of the Department's recent operations at Mayapán, Ruppert and A. L. Smith joined in the tremendous task of recording the several thousand dwelling type structures at that site and in the immediately surrounding area, extending their survey to include comparative material from other areas in Yucatán. It is safe to say that the records accumulated by these men comprise the largest body of information on the domestic architecture of the Maya now in existence. It was the analysis of this material, data that will be used by Smith in a forthcoming monograph, that engaged Ruppert up to the time of his retirement. His wide experience and friendly help will be missed.

At the close of the period under review, Gustav Strömsvik, second only to Ruppert in length of service, retired. His association with the Institution, beginning early in 1926, covered a span of more than 31 years. Strömsvik's abilities proved to be so varied that he was called upon to perform many tasks not strictly archaeological in nature. In his early years at Chichén Itzá he assisted in building the then growing camp, and for a number of years was responsible for the operation of all mechanical equipment there, a task requiring no small ingenuity because of limited supplies and facilities. He worked with Morris on the difficult engineering problem of supporting an overlying temple while one beneath it was being excavated. In 1934, first working under Morris but later in charge, Strömsvik re-erected, repaired, and stabilized a number of the huge monolithic monuments at the ruins of Quiriguá in Guatemala, an achievement that quickly led to his being called upon to do similar work at Copán, Honduras, and to carry out the even greater task of deflecting the Copán River from eroding away the magnificent acropolis at that site. Between archaeological field seasons he built and installed a small museum in the village of Copán, and supervised the construction of an aqueduct to serve the village, thus providing a public facility beyond the reach of the community without his assistance.

Strömsvik's archaeological activities have covered a wide range. In his early years in Yucatán, he participated in expeditions to Quintana Roo and southern Campeche. During the summer and fall of these years, when excavation was at an end in the tropics, he

worked with Morris in the Southwest of the United States. In 1933 he carried out the work of consolidating a part of the building known as the Temple of the Phalli at Chichén Itzá. His work at Quiriguá, already mentioned, included excavation and the making of plaster casts of some newly discovered and unusually fine monuments there. At the magnificent ruins of Copán, where from 1935 to 1942 he was in charge of the co-operative undertaking by the Institution and the Government of Honduras, the entire valley was explored and mapped, large-scale plans and sections were made of the ruins, and Temples 11 and 22, the Ball Court, and the Hieroglyphic Stairway were partly restored. The result of this work was the declaring of the ruins a national park by the Government of Honduras.

Strömsvik served with the Norwegian Navy during World War II. Upon his return from, that duty he soon was occupied with a variety of archaeological assignments. In 1946 he assisted the United Fruit Company operations at Zaculeu in Guatemala; in 1947 and 1948 he participated in the United Fruit Company financed Carnegie Institution-Mexican Government expeditions to Bonampak, Chiapas being in charge the latter year; in 1949 he carried out an archaeological reconnaissance at the ruins of Asunción Mita in Guatemala. With the beginning of our recent operations in Yucatán, Strömsvik saw to the purchase and supply of the new equipment needed and supervised the construction of our field headquarters. During five seasons of operations there he was responsible for the proper functioning of all equipment and at the same time had charge of our program of stabilization of a limited number of structures in the ruin of Mayapán. He also participated in expeditions to southern Yucatán and into Quintana Roo, and carried out exploratory work in the Cave of Dzab-Na, Tecoh, Yucatán. Lastly, it fell to his lot to dismantle our field camp at the close of our operations in Yucatán.

Few careers have been more varied. No task has been too large to undertake, no task too small to deserve his attention. In his native Norway, where Strömsvik has retired, he plans to occupy himself with archaeological problems of that land. His colleagues and his host of friends on this side of the Atlantic wish him well.

NOTES

1. A similar correction should be applied to the dates published in [Chapter 1.45].

H.E.D. POLLOCK

Department of Archaeology

YB 57:435–449, 1958

THE PAST

In this final report it seems appropriate to review the past activities of Carnegie Institution of Washington in anthropology and archaeology. This is a history of over 50 years of research, the results of which fill something like 100 volumes of Institution publications and of course many papers published elsewhere. It is clear, then, that in the space of the next few pages we must view this great body of work from a distance, omitting all detail, seeking out trends and stages of development in research, to the loss, unfortunately, of many a fine discovery, and to the further loss of much of the flavor and excitement of the work.

Upon the incorporation of Carnegie Institution, early in 1902, the Executive Committee, acting under instructions of the Trustees to determine what work should be undertaken, proceeded to appoint a number of Advisory Committees. Eighteen such committees, covering areas in the humanities, the sciences, and the social sciences, were named. One of these was for anthropology. It consisted of W. H. Holmes, Franz Boas, and G. A. Dorsey. It would have been difficult, if not impossible, to assemble three more celebrated anthropologists.

The report of this committee, published in *Year Book 1*, is not without interest as we view it from the vantage point of 50 years. One senses that these men were uneasy in being called upon to review so vast a subject and to compress their findings in the space of a few pages. Touching upon the broad field of anthropology, the subjects that come under that discipline, and the work then being carried on in the Americas, the report moves on to suggestions for work by the Institution. Here the subject is treated under the then standard divisions in America: physical anthropology, archaeology, and ethnology. Although the desirability of knowledge of the cultures of Africa, Asia, and the Pacific Islands was noted earlier in the report, all recommendations were for work in the United States. In the light of developments that were to come a decade later, we should like to quote one sentence from the discussion leading to recommendations for work in archaeology: "In Middle and South America much is still to be done, but your committee has only been able to find, and that at the last moment, one person properly qualified for this branch of research."

Of the three projects recommended by the committee's report, two, namely, in archaeology and ethnology were promptly instituted. For the next two years Holmes carried on a search for geologically early remains of man in America; Dorsey concerned himself with the ethnology of the American Indian for the following five years. We cannot refrain from noting that being "in on the ground floor" was not without its advantages, and that a sort of nepotism within committee was not below such giants as Holmes and Dorsey.

In spite of the fact that the Advisory Committee on Anthropology had made no specific recommendation for work outside the United States, research in Old World archaeology promptly got under way. In response to a commission by the Institution, a rather full report on the opportunities for archaeological researches in the lands of the eastern Mediterranean appeared in *Year Book* 2. Even before this report was prepared, however, two projects concerned with the archaeology of the Near East had begun. One of them, the expeditions of Raphael Pumpelly to Turkestan and his excavations at Anau, carried on in 1903 and 1904, stands not only as a high point in the researches fostered by Carnegie Institution but as a shining light in the archaeology of the Near East. Properly controlled excavation and detailed recording rolled back the centuries to times previously undreamed of, and with the two-volume report (Pumpelly 1908) that followed, the prehistoric archaeology of the Near East left the realm of fancy and entered the more rigorous climate of fact.

With the exception of Pumpelly's expeditions in Turkestan, researches in anthropology and archaeology during the Institution's first decade seem to have been a matter of not infrequent but relatively small grants to individuals. Researches were wide-ranging in area and in subject. The ethnology of the American Indian and the search for geologically early man in America have been mentioned. Other studies involved Oriental art, Near Eastern, Egyptian, and Nubian archaeology, Classical archaeology at Rome and Athens, and archaeology and linguistics in Polynesia. It seems to have been a period of supporting the competent individual interested in worth-while research. There appears to have been no coherence among the various projects, no over-all plan as to what direction archaeology and anthropology might take under Institution auspices. Projects tended to run for about five years, but with no set term. An exception was the work of E. B. Van Deman in Roman archaeology, which continued for many years.

In 1913 the Institution published *Reports Upon the Present Condition and Future Needs of the Science of Anthropology*, which consisted of papers by W.H.R. Rivers, A. E. Jenks, and S. G. Morley that not only reviewed

the status of anthropology at that time but also made recommendations for future work. It is interesting to speculate as to which of the three plans of research presented in those reports would today be considered the most stimulating, potentially the most productive of results, and the most suitable for undertaking by Carnegie Institution. Whatever the choice might now be, Morley's project, which called for intensive archaeological research at the Maya ruins of Chichén Itzá in Yucatán [Chapter 1.1], was approved by the Trustees, who, in so doing, pretty well set the course of the Institution's work in anthropology and archaeology for the next 45 years. With the exception of Van Deman's researches in Roman archaeology, and a few sporadic projects, notably one dealing with Kamchatka and the Aleutian Islands, all other work in anthropology was terminated and for the next 15 years attention was directed almost solely to the archaeology of the Maya.

The following year, 1914, Morley was appointed Research Associate in American Archaeology, a title that was shortly changed to Associate in American Archaeology. Although his plan had called for intensive work at Chichén Itzá, and that to be done on a sizable scale, the project was not to be put in operation for another decade. It will be remembered that this was the revolutionary period in Mexico, and conditions were not auspicious for establishing a long-term contract with the government of that country or the initiating of large-scale operations. It is further possible that the Institution felt some stringency of available funds and a lack of available and competent staff for the project. At all events, research in Maya archaeology was supported by a series of minor grants until 1921 or 1922, when the work reached a scale demanding support by large grants.

The time for intensive work at the ruins of Chichén Itzá not being ripe in 1914, Morley suggested, and received approval for, "a work containing descriptions and decipherments of all known Maya texts." Hieroglyphic research was the side of Maya archaeology nearest to Morley's heart, and remained so throughout his life. Not content with the then known body of glyphic material, he soon proposed to the Institution, and again received approval, that further field work be undertaken. For the next half dozen years, sometimes alone, sometimes with one or two companions, Morley conducted extensive, indeed indefatigable, explorations, often under the most trying and even dangerous conditions. His travels took him time and again into the jungles of the Petén region of Guatemala, time and again to the great ruins of Copán, down the Chamelecón River valley in Honduras, along the eastern coasts of Honduras and Nicaragua, to Costa Rica, and to Yucatán. New sites were discovered, and many

new hieroglyphic inscriptions were recovered. An event that was to have considerable effect on the future work of the Institution in archaeology should be mentioned, namely the discovery in 1916 of the ruins of Uaxactún with "the oldest monument yet reported from the Maya field." In 1920 appeared Morley's huge monograph *The Inscriptions at Copán*, it being realized at that time that the corpus of Maya hieroglyphic inscriptions had grown so large, and knowledge concerning them so extensive, that the original idea of publishing all known Maya texts in a single work was not practicable.

The Institution's interest in Maya archaeology had grown by 1921 to require the annual appropriation of a large grant. Although the nature of the research did not materially change for the next three years, the scope was expanded. Limited excavations were undertaken, and archaeology was supplemented by brief studies in linguistics and agronomy. In 1922 the President notes (YB 21), "It is also of much importance to us in the near future to expand considerably our program of studies in the field of Middle American Archaeology." In 1923 a 5-year permit, supplanted in 1925 by a contract of similar term but with the option of renewal for another five years, for archaeological research in Guatemala was obtained from the government of that country. A ten-year contract was entered into with the government of Mexico. The way was now prepared for the larger and different type of operations that the Institution was about to undertake.

This second decade, 1914–23, of anthropological research may be characterized somewhat as follows. In the first place the Institution had set itself squarely in the field of Middle American archaeology and had put aside nearly all other anthropological activities. The nature of the work was primarily exploration and hieroglyphic research. A number of new sites and many new monuments with hieroglyphic texts had been discovered. The broad outlines of Maya history as conceived by Morley in 1913 had not substantially changed during the decade, but detail had been added, and a very considerable body of new material had become available for future studies. The first volume of Morley's (1937–38) great work on "descriptions and decipherments of all known Maya texts" had appeared, and a site report and archaeological area study was in press.

It is not surprising that in the 10 years that had intervened since Morley presented his plan calling for intensive work at the ruins of Chichén Itzá his ideas as to what would constitute an adequate attack on the problems of Maya prehistory had changed. In the Institution's original permit from the Guatemalan government permission was granted for excavations at Uaxactún, Piedras Negras, and Tayasal, in the Depart-

ment of Petén. The final contract omitted mention of Piedras Negras but included exploratory privileges at all other sites in the Petén. The contract with the Mexican government specifically named Chichén Itzá. Morley's purpose in selecting these three sites [Chapter 38.9] was to bring under study the entire range of Maya history.

Two principles, that if not unique were at least novel at that time, were set forth in Morley's 1913 plan. The first was that the Institution, cooperating wholeheartedly with the antiquity laws of the country, should make no effort, by permission or otherwise, to export any objects discovered, but should return them all to the appropriate governmental authority once their study was completed. The second was that the excavator had an obligation to preserve the remains uncovered from further deterioration. Reconstruction of architectural remains was specifically mentioned. Undoubtedly this farsighted policy was instrumental in our gaining contracts with governments that at that time were far from reassured about gringo motives, and was further instrumental in maintaining extraordinarily cordial relations with those governments. It also set a standard for other organizations practicing archaeology in Middle America.

Morley's dream of intensive archaeological work at Chichén Itzá became a reality in 1924. Large-scale excavations, followed in due time by consolidation and restoration of buildings, began that year and continued almost uninterruptedly for the next decade. A dozen or more structures were rebuilt or repaired to varying stages of completeness. Many more were tested by means of minor excavations, and scores were examined for all that could be learned from what was visible above ground. At the ruins of Uaxactún, after a preliminary survey of the site in 1924, intensive work got under way in 1926 and continued for a dozen years. One huge complex of related buildings was completely excavated, several lesser structures were similarly treated, and many others were uncovered to varying extent. Parenthetically, the contemplated work at Tayasal, where preliminary excavations had been carried on in 1921 and 1922, was never undertaken. Along with the large scale excavations at Chichén Itzá and Uaxactún, exploration elsewhere in the Maya area continued. Year after year expeditions pushed into the little-known regions of British Honduras, the Petén, the Usumacinta drainage, Campeche, Yucatán, and Quintana Roo. New sites were discovered; previously known sites were newly explored; many new hieroglyphic texts were recorded. Morley's hieroglyphic research continued unabated.

Although the work outlined above continued well beyond 1930, quite a different program of operations began in that year, and it seems well to review the

period 1924–29 before moving on. By and large these years were characterized by intensive excavation, restoration of large architectural remains, exploration, and hieroglyphic research. Excavation and restoration on any such scale were new to Maya archaeology and virtually unparalleled throughout Middle America. Equally new, although far less dramatic, were the beginnings of the systematic study of the lesser artifacts of the Maya. Previous to this time Maya studies had been concerned primarily with the hieroglyphic texts, the documentary history, and the spectacular art and architecture. Earlier excavations had turned up pottery and implements of stone, but these had gone largely unstudied. In 1926 the late George C. Vaillant undertook the study of pottery remains collected under stratigraphic controls at Chichén Itzá, and in the following year he produced a doctoral thesis dealing with the chronological significance of Maya ceramics. Good-sized excavations were now under way at Uaxactún, and pottery was appearing in quantity. In 1928 Vaillant visited Uaxactún, and in the few days he was there sank a small pit through successive plaza floors and into the underlying earth. The pottery that came up was not Maya in the sense of what had until then been thought of as Maya pottery; it was akin to the early Archaic pottery of the Mexican and Guatemalan highlands. It was, moreover, obviously earlier than the structural remains above, which in turned were considered to be the earliest discovered up to that time. A whole new horizon of Maya prehistory appeared in the bottom of that pit, and the systematic study of ceramic remains was well on its way.

Clearly, the Institution's interest in archaeology at this time was active and was growing. Indeed, it was not confined to archaeology but included the whole history of man and his works. In 1923 the President wrote:

The plan of study of Chichén Itzá concerns the broader problem of early American history as it can be interpreted through the Maya civilization. Along with specifically archaeological investigations touching the history of engineering, architecture, art, and the stratigraphic sequence of cultures, the researches will include a study of the physical characters of the race and of the environment in which it developed. In order to understand these people as they lived and to secure information concerning their industries and their agriculture, it is necessary to know the limitations imposed by geological, climatological, and other physical conditions determining the development of the plants and animals upon which the inhabitants were dependent. The studies proposed will naturally require the assistance of a considerable group of specialists and it is hoped that through coopera-

tion of other agencies and institutions interested in this work a thoroughly fundamental investigation may be carried out.

The broad study outlined in that paragraph was not to come for some years, but it apparently was held steadily in mind. The person who finally was to implement the program was A. V. Kidder. In 1926 Kidder, who had earlier been retained in the capacity of adviser on the archaeological work of the Institution, was appointed Research Associate, and the following year Associate in charge of archaeology. In 1929 he was named Chairman of the newly formed Division of Historical Research. The Division, which was an administrative grouping of most of the humanistic studies being carried on by the Institution, consisted of the Section of Aboriginal American History, Section of United States History, Section of the History of Science, and Associated Investigations in Palaeography and in the History of Greek Thought. This organization of the Division was to change over the years, notably by the termination in 1936 of the Section of United States History and the substitution in its place of the Section of Post-Columbian History. As our prime concern here is the work in archaeology and anthropology, we shall follow the course only of studies that in one way or another relate to the history and culture of aboriginal man.

Kidder immediately set about organizing the many-sided approach to the study of man that had been envisioned by the President. In 1930, the first year of operation under the new Division, there were either in operation or in process of organization studies in archaeology, epigraphy, physical anthropology, medicine, social anthropology, linguistics, aboriginal documentary history, colonial history, and environmental studies involving plant and animal biology. To this list, over the years, were added studies in ceramic technology, geography, geology, and agronomy. A good part of the work was cooperative in nature, notably with the University of Chicago and the University of Michigan. The central effort focused upon Middle America, and particularly the Maya area, but other work, primarily archaeological, was carried on in the Southwest of the United States.

Even to list the many activities, not to mention their results, under this widespread program of research would go beyond the limits of our report. The largest effort in manpower and resources went into Middle American archaeology, and this part of the work, which will be mentioned again, came nearest to acting as a unifying force in so varied a program. During the dozen years from 1930 to the entry of the United States into the war, certain parts of the program operated virtually continuously. This was of course true of

the work in archaeology, both Middle American and Southwestern. It was also true of the work in social anthropology and the linguistic studies, which dealt with both lowland and highland Maya peoples. Studies in the aboriginal documentary history of the Maya and the colonial history of the Maya area, which were begun in 1931, also continued throughout this period. Research in ceramic technology, begun in 1934, went on without interruption. Work in physical anthropology, medicine, and the environmental studies of biology, geography, geology, and agronomy were carried on for shorter lengths of time. There are excellent reviews of this work as it progressed in Kidder's annual reports during that period [Chapters 1.18–1.30 this volume], notably in [Chapter 1.28 this volume]. Here we shall turn to an account of the archaeological researches.

Before taking up the Institution's central effort in the Maya area it should be remarked that near the beginning of the period we are now reviewing the Institution entered a new archaeological field, namely, the Southwest of the United States. This work was carried on by the late E. H. Morris, who had been in charge of excavations at Chichén Itzá from 1924 to 1928. The field work centered in the northern parts of Arizona and New Mexico and southern Colorado. These researches, which continued uninterruptedly until Morris's retirement in 1955, were never a large effort compared with that in Middle America, but nevertheless were highly productive. Particularly worthy of mention is Morris's elaboration of our knowledge of the early Basketmaker II period of Pueblo culture, and his discovery of remains that, through dendrochronological methods, allowed the chronology of the northern Pueblo area to be carried back to a time before the Christian Era.

Returning to the archaeological program in Middle America, it has already been mentioned that intensive work continued at Chichén Itzá and at Uaxactún until the mid 1930s. With the tapering off of activities at Chichén Itzá, a somewhat similar project, jointly sponsored by the Institution and the Honduran government, and involving excavation and stabilization of buildings and monuments, was instituted at Copán. There was also a small project for the repair and stabilization of monuments at the ruins of Quiriguá in Guatemala. As has been mentioned above, stratigraphic methods of excavation, particularly applied to pottery and other lesser artifacts and especially fruitful in connection with the work at Uaxactún, were under way. Activities of this sort were likewise carried on in British Honduras. The importance of this work cannot be overstressed. From Uaxactún emerged a chronological sequence of architectural styles and pottery types (A. Smith 1950; R. Smith 1955), the latter ably reinforced by the work in British Honduras, that

is fundamental to our knowledge of Classic lowland Maya culture.

Exploration, continuing actively, involved not only individual sites but surveys of sizable areas, notable examples of the latter being expeditions into the hill regions of Yucatán and Campeche and to southern Campeche and southern Quintana Roo. Work of this sort extended as far as southern Veracruz, where a cooperative effort with the Mexican government was undertaken. Hieroglyphic research, always the primary interest of Morley, was now reinforced by the unfortunately brief but brilliant work of J. E. Teeple, and the equally brilliant and long-continuing work of J.E.S. Thompson. Last, there were studies concerned with the simple, domestic houses and the living patterns of the people, aspects of Maya culture that had largely been disregarded until this time. As will appear in subsequent pages, these studies foreshadowed the work of the Department in later years.

So far we have been referring to researches restricted for the most part to the Maya lowlands. Almost by definition Morley looked upon Maya civilization as a lowland phenomenon. That this position might be open to question was suggested by the knowledge that Maya-speaking peoples had inhabited the Guatemala and Chiapas highlands at least since the Spanish conquest and the suspicion that they had been there for many centuries before that event. At Uaxactún the deeply buried ceramic remains, whether considered to be Maya or not, intimated highland-lowland connections at an early time. At all events, in 1930 we find Kidder raising the question whether it might be desirable to undertake excavations in the Guatemala highlands. A more definite statement to this effect by the late O. G. Ricketson appeared the following year, and archaeological survey and excavation began in 1932. With these gradual and rather tentative moves the Institution broadened its archaeological program to include the Maya highlands, an area that was at the same time being brought under study by a number of other disciplines in the overall program of the Division of Historical Research.

Archaeological researches in the highlands, which continued almost without interruption for approximately 20 years, included both excavation and survey. A good part of the work centered in the great ruin site of Kaminaljuyú, lying on the outskirts of Guatemala City. The choice of this site was in part planned, in part fortuitous, owing to modern building operations and public works incidental to an expanding Guatemala City. Important archaeological remains were being uncovered willy-nilly, and there was pressure on the Division's staff from the local governmental office in charge of archaeology, as well as the urgings of professional responsibility, to see that

knowledge of such remains was not forever lost. Indeed, it was uncontrolled digging by local people that led to the Institution's undertaking an operation that stands as a milestone in Middle American archaeology. The work of Kidder, Jennings, and Shook (1946) in 1936, 1937, 1941, and 1942 at two inconspicuous mounds at Kaminaljuyú resulted in the formulation of a time-space network that linked the great Classic centers of Middle American culture in the Valley of Mexico, the Valley of Oaxaca, the Guatemala highlands, and the Petén lowlands. Not only were breached the artificial boundaries that had seemed to surround lowland Maya civilization, but for the first time the high cultures of Middle America came into focus in time and space as parts of one great area of relatively homogeneous, or at least interdependent, civilizations. It is hardly possible to exaggerate the effect of these discoveries on Middle American archaeology.

Inasmuch as the entry of the United States into war late in 1941 severely disrupted the normal activities of the Institution, the archaeological and allied researches being no exceptions, it seems well to pause here in an effort to characterize the work of the dozen years from 1930 through 1941. Certainly the epitome, the very essence, of the program was its many sided approach to the study of man. Time and again in annual reports to the Institution and in papers published elsewhere Kidder presented the rationale and the philosophy underlying that approach. They may be stated somewhat as follows: that human history is a continuum, beginning in the unknown past and still in the making; that man's actions and his culture are intelligible only when focused against his environment; that the story of man can be recovered and properly told only through the aid of researches under various disciplines. To attempt even to summarize the results of this broad program would exceed the limits of the present report. Kidder has gone a considerable way in doing this, unfortunately in an unpublished report, and Morley (1943) has treated the more strictly archaeological activities. Here we must content ourselves with brief comments on the work directly related to anthropology and archaeology.

As mentioned earlier, research in social anthropology was carried on in the Maya lowlands and the highlands. It started in Yucatán, and by the end of the period we are reviewing several volumes and a number of papers covering the results of the work had appeared. Little had been published up to that time on the Guatemala highland studies, but a sizable amount of material had been amassed that was to appear later, although not under Carnegie Institution imprint. Even though most of this work with modern Maya culture was not historically oriented, and its connections with the central historical and archaeological program were

at the time somewhat tenuous, it did point out problems that were subject to, and that since have been brought under, archaeological investigation.

Linguistic research, which had gone on since the beginning of the period and had covered an extraordinarily wide range of Mayan-speaking peoples, was abruptly terminated, temporarily, by the untimely death in 1941 of M. J. Andrade, who had been in charge of that part of the program. Andrade left extensive records, including a nearly completed manuscript of a Yucatec grammar, but virtually nothing had been published.

Studies in physical anthropology were never a large part of the program. Some work had been done on the living Maya of Yucatán, resulting in two publications. There were also the descriptions in archaeological reports of the none too plentiful human skeletal remains produced by excavations.

Research in aboriginal documentary history, primarily concerned with preconquest times in contrast to colonial history and hence more directly applicable to archaeological researches, was highly productive. By the end of the period we are considering, two translations of important Yucatecan Maya documents, magnificently annotated, had appeared, and a third, more general volume (Roys 1943) dealing with the history of Yucatán at the time of the Spanish conquest appeared two years later. This work, which was of particular value to hieroglyphic research, did much to advance our understanding of the social, religious, and intellectual content of Maya culture, knowledge of a sort that is so difficult to wring from the material remains of a past civilization.

It has previously been mentioned that the hieroglyphic researches of Morley were amplified at this time by the efforts of Teeple and of Thompson. The work of these men resulted in a fundamental change in prevalent reconstructions of Maya history. The Morley-Spinden correlation of the Maya and Christian calendars, the most widely accepted correlation up to that time, was quite generally abandoned in favor of the later Goodman-Martínez-Thompson correlation. The effect of this change, which tended to be confirmed by certain archaeological discoveries, was to place the beginnings of Classic Maya civilization around A.D. 300 instead of near the start of the Christian Era. This led to surrendering the long held idea that the northern Yucatán development of Maya civilization, the so called New Empire, came about only after the abandonment of the great southern centers, located in the so-called Old Empire, and substituted the idea that the northern cities were at least in part coeval with the Old Empire. During this period Thompson was busily working with, and publishing papers on, new interpretations of hieroglyphs, work

that was to bear even heavier fruit in later years. In 1938 appeared Morley's great 5-volume compendium, *The Inscriptions of Petén*, the second major contribution to his lifetime task of compiling "a work containing descriptions and decipherments of all known Maya texts."

We have already touched upon the general course of the archaeological work during these years. Here we should like to point to trends that characterized the period and to certain fundamental advances in our knowledge of Maya civilization. It will be remembered that intensive excavation and the restoration of architectural remains had been continuing much as in the previous decade. As the period progressed, however, this form of activity began to taper off. Exploration went on, but took more the form of area surveys in which the discovery of new sites was incidental to acquiring a knowledge of the area rather than an end in itself. There were the beginnings of studies concerned with the domestic houses and living patterns of the people, a new development in Maya research and one that was later to become extremely popular in American archaeology. Ceramic technology, the scientific study of the physical properties of pottery, was yet another new approach to archaeological problems. Almost certainly the most important aspect of the work of this period was the steadily increasing emphasis on "dirt" archaeology, the use of stratigraphic techniques of excavation to develop sequences of architecture, artifacts, and pottery.

There was also the important matter of extending the work to the Guatemala highlands. Two earlier fundamental misconceptions of the prehistory of Middle America were thus corrected. The idea that Classic Maya culture had its immediate beginnings in the highlands, whence it was carried to the previously uninhabited lowlands, was clearly untrue, as shown by the long sequence of Preclassic, and surely indigenous, pottery underlying the Classic levels at Uaxactún. Secondly, the idea that the Maya were the first "civilizers" in Middle America, that they had given high culture to other peoples, was no longer tenable, for the widespread chronological equations established by the finds at Kaminaljuyú demonstrated that the Classic phases in other cultures were roughly coeval with that of the Maya, the earlier, underlying phases apparently being autochthonous. Lastly, it should be noted that Maya civilization was no longer looked upon as an isolated phenomenon but was regarded as one of the several high cultures of Middle America and as a part of the aboriginal civilization of the whole area. These were fundamental changes in thinking.

We are not sure that we have sufficiently stressed the size and the uniqueness of the program of historical researches that the Institution had begun in 1930. This program, moreover, was not simply large; it was

diverse, and it was experimental. Even omitting the studies outside Middle America, the only unifying force that applied to all segments of the work was the common area of operation. Unquestionably, some of the environmental studies had little regard for whether man had ever inhabited those parts or not. Some of the studies concerned with man had little interest as to his earlier, or perchance later, activities than those upon which the work focused. This is not to say that all studies were not providing knowledge pertinent to the understanding of man's career in Middle America. Virtually without exception they were. The problem was how to pull all this knowledge together, how to synthesize the results of the work, how to shape the great accumulation of knowledge, or potential knowledge, to the long-range purpose of the program—the story of man through the ages in Middle America. The more distant purpose, the effect and usefulness of that story in the over-all study of man and his works, was yet another matter.

It is clear that Kidder was well aware of the magnitude of these problems. In a number of his annual reports he points out the difficulty of coordinating such widespread researches, the problem of correlating and interpreting the results, the experimental nature of the program, and the need for an arbitrary time limit against the initiation of new work and for the completion of old. In his 1939 report [Chapter 1.27 this volume], following a review of the first 10 years of operation of the Division, he restates much of his earlier thinking on these matters and suggests a termination of researches and synthesizing of results over the following decade (YB 38). Before this report appeared in print war in Europe had begun, and two years later this country was actively involved.

It is hardly necessary to point out the disruption of research and plans for research occasioned by the war. Quite aside from war, however, there were, and had for some time been, other forces at work that gravely affected the Division's operations. The broad program of allied researches envisioned by the President in 1923 and put into practice in 1930 had been predicated upon the expenditure of large sums of money. As the years went by and the costs of all research increased, it became progressively more difficult to finance so large an undertaking. Even at the peak of expenditures appropriations for the Division's work were approximately 20 percent below the figure originally contemplated, and during the decade they averaged some 25 percent below it. With the outbreak of war financial matters gave way to more pressing problems, but it became clear that in the future there would have to be a reappraisal of the activities of the Institution in general, and more specifically, from our point of view, of whether the broad program of historical researches

involved a larger proportion of its resources than the Institution cared to allocate to such work.

At the end of hostilities the members of the staff of the Division, along with millions of other people, found themselves in a very different world from that of a few years earlier. The difference that concerns us here was a new climate in which to carry on their work. In his annual report for 1946 [Chapter 1.36 this volume], we find Kidder discussing the war's disruption of plans for an orderly termination, in the late 1940s, of the Division's program of researches, the need for reducing the extent of the Division's activities in the future, and the desirability of promptly formulating recommendations to the Institution for a new program of work to follow the termination of the old. The first of these problems can best be taken up in describing the research activities of the Division during the war and postwar years. In regard to the second problem, it can simply be stated that by the end of 1950 all activities of the Division not directly related to archaeology had been concluded. Lastly, after a series of staff meetings, a new program of research, which will be described later, was presented to the President in 1947 and was approved in 1950.

Some research was, of course, carried on during the war. The work in social anthropology continued, although on a reduced scale. Hieroglyphic research went on without severe interruption. A project concerned with the architecture of the Maya, started just before the war, was brought to fruition in one of the Division's finest publications (Proskouriakoff 1946). In the matter of archaeological field work, the winter of 1942 was active, mainly because a number of parties were already in the field, or on the point of departure, at the time of our entrance into the war. One such project, moreover, developed information of considerable importance to our understanding of Maya history. In his ceramic survey of Yucatán the late G. W. Brainerd found in a number of sites in the northern part of the peninsula Preclassic, or Formative, period pottery. It will be remembered that a few years earlier the change in thought about the correlation of the Maya and Christian calendars had tended to push back in time the beginnings of civilization in northern Yucatán, but no one had thought very seriously of such beginnings as being earlier than the Classic period. With Brainerd's discovery it became evident that the northern culture was just as deeply rooted as that of the south, and equally indigenous. After the 1942 field season almost nothing was done except for some explorations in 1944. The preparation of manuscripts and publication of results of research, of course, continued through the war period.

Turning to the postwar years, it will readily be understood that the general process of contraction of

the activities of the Division and the necessity of terminating in the space of five years a large and badly disrupted plan of researches left no place for a coordinated program of field work. Primary stress was upon the completion of earlier projects and upon the publication of the results of past research. How well this was accomplished is indicated by the appearance, from 1946 to 1950, of no less than 12 volumes in the Institution's monograph series, with eight more, all based on earlier work, to appear over the following five years. There were, moreover, other publications not under the Institution's imprint. Such field work as went on was mostly in the Guatemala highlands. It consisted mainly of archaeological survey and limited excavations. Somewhat more intensive digging, to a considerable extent unplanned in that it frequently originated from chance finds brought about by industrial and civic excavations, was carried on at the ruins of Kaminaljuyú on the outskirts of Guatemala City. The results of this work were extraordinarily profitable in that there was developed and defined a long sequence of Formative cultures extending considerably further back in time than had previously been known. An understanding of the relatively high development of Formative culture, moreover, did much to explain the apparently abrupt flowering of culture in succeeding Classic times. Another field project of major importance, also brought about by a chance find, was the recording and study of the now famous wall paintings at the lowland Maya site of Bonampak (Ruppert, J. Thompson, and Proskouriakoff 1955).

It was mentioned earlier that hieroglyphic research continued relatively uninterrupted during the war and postwar years. This work was in part terminated in 1948 by the death of S. G. Morley, founder of the Institution's researches in Middle American archaeology, for 35 years a member of the staff, and a lifelong student of Maya hieroglyphic writing. There nevertheless appeared in 1950 the Institution's third great work on Maya epigraphy (J. Thompson 1950), this one by J.E.S. Thompson. Last, we should mention a project begun toward the end of the war that introduced a new method in the study of Maya sculpture. There is every chance that this work (Proskouriakoff 1950) will stand as a milestone in the study of aboriginal Middle American art.

Certain activities of the Institution during this period, although not of a research nature, should be recorded. These included the assistance given to the government of Guatemala in establishing a museum of archaeology and ethnology and in the organization of a national institute of anthropology and history. Such activities, carried out on an unofficial level, constitute international cooperation of the best sort. Indeed, the entire history of the Institution's work in Middle

America has been one of friendly dealings with governmental agencies and sincere cooperation with foreign colleagues. Surely not the least of the Institution's accomplishments has been the stimulus provided to the study of anthropology and archaeology in the countries where it has worked.

In reviewing this period of approximately a decade that included the war and postwar years, certainly the outstanding factors affecting the work of the Division were the disruption of research caused by the war and the change in thought by the Institution as to the part historical research should play in its over-all program of activities. In the first place, the long considered and carefully laid plans that called for an orderly termination of the many and diverse studies under the historical program, to be followed by summation and synthesis of results, upon which were to be built recommendations for future work, were badly thrown awry by the war. Fortunately, there was time to bring the great majority of projects, with a few outstanding exceptions, to the point of publishing definitive results, but there was no place for summation and synthesis of the results of the whole, wide program of studies. Second, the rapid retrenchment during the closing years of this period left the Division engaged almost solely in archaeology, with ceramic technology and a tenuous connection to aboriginal documentary history as the only collateral researches. This was, of course, a vast change from the large and expanding program of the 1930s.

In view of the difficulties that had to be overcome during these years, the results of the work were considerable. Of outstanding importance was the knowledge acquired of the Formative cultures of the Guatemala highlands and of Yucatán, and the light it threw upon the origins and development of Classic civilizations. Hieroglyphic studies had been measurably advanced, and a new approach to the study of pre-Columbian art had been created. Last, a large body of factual and definitive material had appeared in a long series of monographs and other published reports arising from the work of the Division.

Late in 1950 A. V. Kidder retired and the writer was appointed Director of the Department of Archaeology, the successor organization to the Division of Historical Research. The suggested program of operations, already mentioned, that had been presented to the President in 1947, had by this time been approved; it is presented in some detail in the annual report for 1951 [Chapter 1.40 this volume]. The program was designed to be compact and to reach the stage of drawing conclusions in a predictable number of years. It was, of course, based primarily on archaeology but with considerable reliance on the results of previously performed historical research. The locus of the work

was the Yucatán peninsula, and the period under consideration was the approximately five centuries preceding the Spanish conquest. The focal point of field operations was the last important center of aboriginal Maya civilization, the ruins of Mayapán. Subsidiary operations were archaeological surveys and exploration in outlying areas thought to be important in the period under study, and an examination of certain known centers of Maya rule after the fall of Mayapán and during the final 100 years before the Spanish completed the conquest of Yucatán. The essence of the program, aside from more usual archaeological objectives, was an experiment in linking the results of archaeological research with the knowledge derived from aboriginal and early Spanish written records in the effort to discover how much of the intellectual, or at least nonmaterial, content of a bygone civilization could be recaptured.

It will be seen from the above that the earlier methods of intensive excavation at one large site, area surveys, and exploration were employed. At Mayapán, after the mapping of the ruins, particular emphasis was given to the study of the secular aspects of the culture, the dwellings of commoner and of noble, and the arrangement of houses within, and on the outskirts of, the city. Comparative work on a smaller scale was carried on elsewhere in the peninsula. Archaeological surveys, particularly stressing ceramics, were conducted in the little-known areas of Tabasco and coastal Quintana Roo. Exploration on a modest scale occurred in Yucatán, Quintana Roo, and along the west coast of the peninsula. Stratigraphic techniques of excavation, now firmly established in Middle American archaeology, were of course used extensively. In recognition of the friendly cooperation at all times offered by the Mexican government, the Institution voluntarily undertook a limited program of restoration of building remains, a project desired by that government.

Outside of archaeological field work documentary research continued, culminating in R. L. Roys' (1957) *Political Geography of the Yucatán Maya*. In his hieroglyphic researches during this period Thompson turned to the gigantic task of compiling a Maya hieroglyphic dictionary, a tool that should be of immeasurable value to future work in this field. Work in ceramic technology went on, resulting in the first definitive presentation of this subject from the point of view of usefulness to the archaeologist (Shepard 1956). Other researches correlative to the central archaeological program were studies in physical anthropology dealing with the human skeletal remains from Mayapán, the identification and study of animal skeletal remains from that site, and the analysis of metal objects. The technique of dating archaeological remains by the newly developed radiocarbon method was also relied upon.

As this program of archaeological and related researches developed, the Institution made the decision to withdraw from the field of archaeology. Fortunately, the program had been shaped to reach the stage of drawing conclusions within approximately five years. Virtually all field work terminated in 1955, and the staff turned to the task of presenting the results of the work for publication.

The writer is hesitant in attempting to characterize the period from 1951 to the present. Not only has he been too closely identified with the work, but he lacks the perspective of time. Certainly one contrast to the preceding 20 years was the contraction in the size of the program and the restricting of the work to relatively clear-cut limits in time and space. Possibly the most important directing influences were the effort to link recorded history, both aboriginal and Spanish, with the results of archaeological field work, and the considerable attention devoted to the secular aspects of the life of the ancient Maya. Operating procedures did not vary in any marked degree from the preceding period, and the use of intensive excavation at one site was the revival of an earlier approach. A new technique, not peculiar to the work of the Institution but employed generally in American archaeology at this time, was radiocarbon dating. Interestingly enough, because of certain radiocarbon dates there has been a marked trend among Middle American archaeologists to return to the previously little-favored Spinden correlation of the Maya and Christian calendars, a shift that affects our reconstructions not only of Maya history but of aboriginal Middle American history in general. Beyond this the writer does not feel that he should go in characterizing the work of the period.

One is even more hesitant about summarizing the results of the recent program. Some eight or nine manuscripts dealing with these results are at present in various stages of completion. The final story must rest on the information they present. In the meantime it seems possible to point to some failures, some successes. The effort to learn something of the last 100 years of aboriginal history in Yucatán, the time from the fall of Mayapán to the final conquest by the Spanish, was almost fruitless. In the matter of linking historical records with the information derived from archaeological field work, and the effort to develop some knowledge of the nonmaterial aspects of Maya civilization, it appears that we may not have gone as far as we had hoped but that our progress was not inconsiderable. In the annual reports of the period we are reviewing and in this Department's series of *Current Reports* will be found a number of references to the archaeological confirmation of previously unproved historical statements and to archaeological evidence concerning the social and religious aspects of Maya

civilization. Chronological and cultural information of the sort normally to be expected from archaeology was of course produced. The time of greatness of Mayapán was well established, the character of its culture was delineated, and the relative chronology of, and the cultural ties, or lack of ties, between, central Yucatán, the east coast of the peninsula, and western Campeche and Tabasco were outlined. Last, but not least, it was shown that the great break in cultural tradition, the precipitous step downward to degeneracy, occurred not with the rise to power, under foreign domination, of the great city of Chichén Itzá, but at the end of that city's time of greatness and with the rise of Mayapán. In broad outline these appear to be some of the results of the work of the past seven or eight years. Amplification must await the definitive reports now in preparation.

THE PRESENT

The work of the present year has, of course, been directed toward the termination of the activities of this Department. The major effort has gone into the preparation of reports presenting the results of our researches. At the end of the year, four such reports were finished, one was nearing completion, two others were well advanced, two were yet to be written. Quite naturally, no new field operations have been undertaken. Several members of the staff did, however, travel outside the country to complete their studies of archaeological collections.

R. E. Smith was in Yucatán approximately six months analyzing the large accumulations of ceramic remains from Mayapán and other sites in the peninsula. This phase of the work is now finished. A statement covering his recent activities appears in a subsequent section of this report. Smith will continue with the Institution for another year in order to prepare a monograph dealing with the pottery of Mayapán.

Aside from her primary task of preparing reports on the architecture and artifacts of Mayapán, Proskouriakoff spent two weeks in Yucatán in a final check of our collection of artifacts. She then continued to Guatemala, where she gave an additional two weeks to the examination of materials in the national museum that will be of value in her forthcoming studies. A report on this work will be found below. She will continue her studies, with the Institution, on the evolution of aboriginal art forms in Middle America.

Shepard, who has divided her time for the past year between the U. S. Geological Survey and this Department, has continued her researches in ceramic technology and in the composition of pigments from wall paintings and pottery decoration recovered from the ruins of Mayapán. During the winter she was able

to spend three months in Yucatán and Guatemala, assisting R. E. Smith with his analysis of Yucatán pottery and rounding out some earlier research on pottery from Guatemala. Her report on this work will be found below. Shepard has recently been appointed geologist in the U. S. Geological Survey. She will continue for the present, however, to give some time to her ceramic technological researches for the Institution.

A. L. Smith has given the greater part of his time to a study of the residential structures and settlement patterns of Mayapán and its environs. In this work he is using comparative data from a number of other important sites in Yucatán. An interesting finding from these studies is the apparent similarity of the ancient groups of buildings, each group within its own walled enclosure, to the walled family lots in modern Indian villages in Yucatán. Some information about the function of structures is also emerging. In anticipation of his future work with the Peabody Museum of Harvard University, Smith spent approximately three months during the past winter in Guatemala, where he participated with Dr. Gordon R. Willey, of Harvard University, in a survey of ruins where the Peabody Museum is considering future operations. Smith left the Institution to take up his new work on July 1, 1958.

Thompson's principal activity during the past year has been the continuation of his catalogue of Maya hieroglyphs. The work of listing all examples of every glyph, other than those of a strictly chronological nature, was concluded some time ago, and for some months past he has been engaged in transcribing this material into a catalogue which records every known combination of main element with affixes and the location on monument or codex of each combination. This is a long and tedious task, for often a main sign can be identified, whereas the smaller affixes, more easily affected by weathering, are difficult to make out. Up to the end of April Thompson had catalogued, with some commentary, 95 main elements, all of the geometric category, representing 4,940 occurrences.

Thompson has also given some attention to locating by means of local glyphs the sites at which certain artifacts, or at least the glyphs on the artifacts, were carved or incised. This study should throw light on local styles and trade routes. At a later date he hopes to publish a short paper on the subject. On his retirement from the Institution in the near future, he will continue his researches in England, where he has taken up residence.

During the past year Shook has remained on leave of absence in order to take charge of the work of the University Museum, University of Pennsylvania, at the ruins of Tikal in Guatemala. With his retirement from the Institution on July 1, 1958, Shook will continue his work with the University Museum.

Shortly after the close of the year under review, Lillian Lawrence, Administrative Secretary of the Department for the past eight years, will leave the Institution. The Director and all members of the staff are deeply indebted to Miss Lawrence for her unfailing assistance, efficiently and cheerfully performed, in administrative and many other matters. She will take up new duties in business.

Several administrative happenings of the last 12 months should be recorded. In November the Director went to Yucatán to effect the turning over of a considerable portion of our archaeological collections to the Instituto Nacional de Antropología e Historia of Mexico and to arrange for the closing on January 1, 1958, of the Department's offices and laboratory in Mérida. The remainder of the collections was delivered to the Instituto, during the past winter and spring. A detailed and carefully arranged documentation accompanied these materials.

The disposing of the equipment and scientific records of the Department, a process that has gone on for several years, was brought to a conclusion by the end of the year under review, with the exception of such materials at our laboratory of ceramic technology at Boulder, Colorado, where Shepard will continue her researches for the present. It has been the policy of the Institution that equipment should be disposed of so as to continue in the uses for which it was originally acquired. Following this policy, gifts have been made to the University Museum of the University of Pennsylvania, to the Middle American Research Institute of Tulane University, and to the R. S. Peabody Foundation for Archaeology at Andover, Massachusetts. The major part of our field and office equipment in Yucatán has been presented to the Instituto Nacional de Antropología e Historia of Mexico. Scientific equipment, office equipment in Cambridge, and virtually all our scientific records have been given to the Peabody Museum of Harvard University, an organization with which this Department has closely cooperated for many years.

In the autumn of 1957 J. Eric S. Thompson was elected a member of the Faculty Board of Archaeology and Anthropology, Cambridge University. Tatiana Proskouriakoff has recently been appointed Research Fellow in Maya Art, Peabody Museum, Harvard University.¹

NOTES

1. Appendices 1 through 4 describe the archival records for the CIW Maya Program available at the CIW headquarters in Washington, DC, and at the Peabody Museum of Archaeology and Ethnology at Harvard University, the University of Chicago Library, and at the Latin American Library at Tulane University [ed.]

2.0. ART AND ARCHITECTURE

2.1.

H.E.D. POLLOCK

Architectural Problems in the Maya Field

YB 30:117–119, 1931

Certainly one of the most impressive facts pertaining to the civilization of the ancient Maya is the extraordinary activity of these people as builders. Any one even moderately well acquainted with the territory occupied by this civilization can not but have marveled at the vast number of ruins that lie hidden on every hand in the dense growth of bush and jungle that covers those parts of Mexico and Guatemala inhabited by the Maya. The narrow trails that traverse this country are continually passing by, or leading over, low mounds and platforms, often difficult to separate from the natural contours of the land, but usually offering some peculiar features to distinguish them as the handiwork of man rather than of nature. The number and extent alone of such artificial hillocks mark the Maya as indefatigable builders, but fortunately for the student there are also many buildings in a sufficiently good state of preservation to show that these people were not only untiring workers, but architects of a relatively high order. The great stone cities of Yucatán and Guatemala, first brought to general at-

tention nearly 100 years ago, and much discussed in recent years, contain many excellently preserved structures; and every worker in the field knows that there are scores of less conspicuous sites containing literally hundreds of buildings in various stages of ruin, many of which offer valuable architectural details to the student.

It is now believed that nearly all surviving Maya structures served in one way or another for religious purposes, but whether this surmise is correct or not, their size and elaboration mark them as works of communal labor; and it seems fair to assume that, outside of work pertaining to the ordinary domestic economy, no other activity occupied, so much of the energy of the Maya as did his architecture.

In two articles appearing in recent *Year Books* of the Carnegie Institution [Chapters 1.17 and 1.18] attention has been called to the need of a general survey of Maya architecture. The importance of this work can hardly be overestimated, but before attempting to discuss any future course of action, it may be well to review

briefly the present status of the Maya architectural problem.

At present there is a very considerable body of published material upon Maya buildings. No serious effort, however, has yet been made to coordinate the available data, the reason presumably being that those acquainted with the literature realize that in its present form it is too fragmentary to provide a basis for an adequate survey of Maya architecture. Dealing with the broader aspects of the situation, our present knowledge allows us to divide the Maya area into eight or nine regions that appear to be characterized by more or less distinctive features of assemblage, construction, or decoration. Because these regions have been associated with certain periods in Maya history through nebulous historical records, and through a somewhat larger and more reliable body of hieroglyphic calendrical inscriptions, it is customary to assign their architectural remains to time periods that accord with the historical and calendrical data; and although some effort has been made empirically to trace the development of architectural forms, our knowledge of the evolution of Maya architecture is still for the most part dependent upon external, rather than internal evidence. In the present embryonic state of Maya archaeology, a situation of this sort is not extraordinary. The possibilities of a short cut to the reconstruction of history offered by the understanding of so fine a time machine as the Maya calendar have of course long been apparent to workers in the field with the result that during the past two or three decades intensive work on hieroglyphic material has obscured the value and caused neglect of such other important lines of research as architecture and ceramics. It is indeed not impossible that the supposed "open sesame" of the calendar may actually have led us into erroneous beliefs in regard to certain aspects of Maya history. The addition, therefore, of another category of evidence, such as it is hoped may be found in architecture, should not only tend to fill the gaps in our present knowledge, but should serve as an extremely salutary check upon hypotheses now current.

Whatever the eventual worth of a survey of Maya architecture may prove to be, and whatever may be the ramifications to which it leads, its immediate aim is to establish one or more sequences of architectural form that will be intelligible both chronologically and geographically in the interpretation of Maya history. A study of this sort should stand as an independent index to the development of Maya culture, to be coordinated with the many other indices which eventually will go to make up the whole story of the Maya; it should stand as an aid to the rest, and not be a passive factor totally dependent upon other lines of research for its own interpretation. This is not to be understood

as meaning that related fields such as calendrical material and ceramics, which may well prove of great aid in building up architectural sequences, should be neglected, but rather that architectural conditions should first be allowed to speak for themselves in creating the desired sequences. It is hoped that, given a sufficiently large and detailed knowledge of the remains, a natural development in forms and practices will become manifest and that in many instances buildings may be assigned to proper chronological position upon internal evidence alone. General laws in the development of architecture have been found to hold true when dealing with other civilizations, and there is no reason to believe that similar laws may not have been operative in the case of the Maya.

As previously intimated, a considerably greater and more detailed knowledge of architectural remains than now exists is necessary, for any comprehensive study. Undoubtedly the first step, is to sift all earlier work, rejecting what is unfit, and carefully to arrange and coordinate the remainder to form a framework, or at least a starting point, for the further information that will be acquired in the field. This review should present opportunity for devising a convenient and efficient system for handling the great amount of material that must be collected. The importance of an intelligent and clear arrangement of data can hardly be overestimated, for unrelated facts mean nothing. Turning to the work in the field, it may be said that the larger aspects of assemblage, construction, practice and decoration must be studied, and that the component parts of buildings must be examined and carefully noted. This means that architectural remains should be treated not only as single buildings, and groups of buildings, but that each structure should, figuratively speaking, be dissected, its elements be recorded by means of drawings and photographs, and the facts thus accumulated by logically ordered for comparative study. Only through detailed analysis of this sort is there any hope of establishing a chain of evolution in architecture. It is quite possible, however, that even this meticulous process will prove insufficient to make clear the development of forms and practices, and the unerring guide of secondary construction in the form of superposition, lateral expansion and renovation should carefully be watched for. A factor militating against uniform development is that of varying environment, especially in the matter of available supplies of building stone. The Maya territory and its architecture are both fairly homogeneous, but local peculiarities must be given consideration from the aspect of environment, and not simply be interpreted chronologically.

At the very outset of any project of this nature, one comes face to face with certain practical considerations that often dictate a course of action quite different from

the theoretical ideal. In the present instance, the ideal would of course be to excavate every building in the Maya area and record all possible information in regard to it. This is obviously impossible. The tremendous quantity of remains, and their general inaccessibility, makes all thought of excavation, other than of the most cursory sort, out of the question; but it is hoped that remains still above ground will provide sufficient material to carry on the study. Not only must extensive excavation be set aside, but at first it would appear advisable largely to restrict work to known sites rather than to indulge in much exploration. When a considerable body of material has been collected, certain obvious gaps in our knowledge will immediately become apparent. Then, exploration particularly dedicated to the filling in of these gaps may be carried on. Accepting these practical considerations of little excavation and restricted exploration, it would not appear to matter greatly in what region operations are begun. The entire area must eventually be covered, and in fact it will probably be necessary to have data from nearly all regions before lines of growth become intelligible. This is merely another way of saying that much must be done before conclusions may justifiably be drawn, and in this statement we have the crux of the problem immediately at hand. With the collection of further material from representative sites of the various regions of the Maya area, and its careful arrangement in conjunction with facts already known, will come both opportunity and necessity for interpretation and inference.

2.2.

ALFRED V. KIDDER
Architectural-Ceramic Survey

YB 31:96-97, 1932

As pointed out in previous *Year Book* reports, the outline of early Maya history has been based upon hieroglyphic dates. Dr. Morley's immediate chronological assignment of Calakmul, on the evidence of such inscriptions, is a case in point. For working out the actual story of the growth and decline of any given city, as well as for the placing of the many Old Empire sites which yield no dates, and practically all the ruins of the New Empire, one must, however, rely upon methods other than epigraphic. For such purposes

ceramics and the details of architectural practice are by far the most easily obtainable and most surely reliable criteria available at the present time. Mr. H.E.D. Pollock has accordingly been devoting himself to the study of Maya architecture and Mr. H. B. Roberts to that of Maya pottery. During the past year they have combined forces to carry on a joint investigation in northern Yucatán, using Chichén Itzá as a base. The team attack has proved most satisfactory. On the practical side it naturally results in marked economy; intellectually it is a great advantage for two men approaching the same problem from different points of view to be able to keep closely in touch with each other's methods and results.

During the season of 1932 Messrs. Pollock and Roberts made three trips; two to the Puuc region south of Ticul, where they worked at Sabacché, Muluc Seca, Xlapak Maler and Labná; one to Yaxuná, a site some 12 miles [19.3 km] south of Chichén, at which the ancient causeway running eastward from Cobá is thought to terminate. Mr. Roberts also at Cobá to supplement, by pottery studies, the architectural observations made by Mr. Pollock in a previous year.

Ceramic research in the Maya area outside the highlands of Guatemala is rendered difficult by the fact that surface sherds are either hidden by rank vegetation or are so weathered by exposure as to be more or less useless. It therefore became evident, early in Mr. Roberts' study, that some method must be developed for easily and economically collecting representative specimens from underground, and particularly for gathering material from places which would yield stratigraphic evidence. As rubbish heaps naturally best fulfill the requirements of abundance of sherds and stratigraphic deposition, he has devoted much attention, at Chichén Itzá and elsewhere, to identifying the spots where the Maya were most given to dumping refuse. The result has been an increasing ability to locate heaps off the edges of terraces, in corners of plazas, in low spots adjacent to temple-groups, etc. His trenches of 1932 at Chichén Itzá, in the Puuc, at Cobá, and Yaxuná have accordingly produced a great amount of broken pottery, so many thousands of pieces, in fact, that one of his major problems has been to keep their cleaning, sorting and classification abreast of their excavation.

Research upon the 1932 sherd collections is still in progress. It can not therefore finally be reported upon, but Mr. Roberts has already been able to recognize many well-defined types, to group these types into regional categories, and even to establish certain definite chronological relationships. In other words, the study of Yucatecan pottery is being placed upon a sound basis. Also, growing familiarity with the wares is permitting, the quicker separation of what is of significance

from what may safely be discarded in the field, thus sensibly reducing the amount of material which must be taken to the laboratory at Chichén Itzá, and so shortening the whole classification process.

In addition to his strictly archaeological work, Mr. Roberts has collected information as to the technique of present-day pottery making in Yucatán.

In his architectural investigation, Mr. Pollock has likewise been faced by difficulties in the collection and recording of data. Buildings abound, but they are, in many cases, so badly ruined that it is extremely hard to determine even their general layout and ground-plan, to say nothing of the details of their structure. Furthermore, while potsherds can be brought in for study, temples unfortunately can not, and full descriptive recording must be done in the field. This involves photography, and the making of sketches, plans and elevations, all time-consuming processes. Mr. Pollock has therefore not found it easy to keep pace, at such large sites as Labná, with the ceramicist. He believes, however, that with the assistance of a collaborator to help with surveying and photography, he can do so. His data, like those of Mr. Roberts, are not yet at a stage permitting conclusion. It may be said, however, that significant architectural diagnostics are beginning to be recognized, and that when similar studies are made of other groups, important regional and chronological differences will become evident. In the meantime Mr. Pollock has developed an extremely efficient method of note-taking and filing which not only permits instant comparison between analogous features of different structures, but which also brings his factual data into proper form for immediate publication.

2.3.

H.E.D. POLLOCK

Architectural Survey

YB 35: 122–125, 1936

In last year's report [Chapter 2.1] it was pointed out that the ruins of the Puuc region of Yucatán were serving as point of departure for the comparative study of the architecture of Yucatán. It was further noted that, while considerable progress had been made toward gaining a knowledge of Puuc architecture, an obvious lacuna was to be found in the lack of any adequate study of the great ruins of Uxmal. In addition,

it seemed desirable that a reconnaissance be made of a number of lesser sites in the Puuc; and lastly, it was pointed out that the small amount of work done outside the area gave promise of highly significant results whenever the survey could be carried into contiguous regions.

The operations of the past season were planned in accordance with the foregoing factors. Work at Uxmal and a rapid reconnaissance of minor sites were to terminate the survey of the Puuc. Keeping in mind the work of future years, the reconnaissance was to be extended to include a number of sites in the very important Chenes region lying south of the Puuc and west of the modern city of Campeche. Necessities of transportation dictated that the Chenes trip come first, at the height of the dry season. As in past years, the architectural and ceramic surveys operated in conjunction.

While previous work had provided a considerable knowledge of the ruins of the central and north-western sectors of the Puuc, little was known of the southeastern and southern ruins. The expedition therefore first visited Chacmultún, one of the larger southeastern sites, and thence moved westward to Chacbolai, Kom, Kiuic, and the little-known remains of Huntichmul I, all of which proved to fall definitely within the tradition of Puuc architecture. At Kiuic were found three stelae, two plain and one with the crude carving of a skeleton; and at Huntichmul I a façade decoration that is common in the Chenes and further south.

The next move was southward to Itsimté. These ruins are very extensive, but due to their proximity to the town of Bolonchenticul they have been so thoroughly robbed of building stone that few architectural details remain visible. Geographically, the site is located in a region that might be expected to form the southern border of the Puuc area, and what little may be gleaned from the architecture seems to be in accordance with expectation, for the remains appear to be essentially Puuc in character, but with certain transitional, or at least exotic, elements not usually associated with the ruins to the north. While the reconnaissance left the Puuc at this point, it subsequently visited two ruins that appear further to delimit the region and thus may be mentioned here. These are Xkichmook and Xculoc, the former lying east of Itsimté, the latter northwest. Like Itsimté, both seem to contain transitional architectural elements, Xkichmook probably drawing from the Chenes area to the south, Xculoc being rather definitely associated with the nearby Xcalumkin region which in turn seems closely related to the Puuc.

Leaving Bolonchenticul and Itsimté, the party moved southeastward to Xtampak, more frequently

known as Santa Rosa Xlampak. These ruins are definitely non-Puuc, and presumably are to be associated with the as yet ill-defined geographical and cultural area known as the Chenes. Xtampak is of great importance. Not only is there a large amount of readily available architectural detail, but during the present season eight stelae were discovered, two of which carry Initial Series that record dates a year or two prior to the katun-ending 9.16.0.0.0. The style of architecture at Xtampak has been used in support of one of the proposed correlations of Maya and Christian chronology, so the occurrence there of dated monuments may prove of value in dealing with the vexed correlation problem as well as in fixing the relative chronological position of a distinctive style of architecture.

With one exception the remaining ruins visited were in the Chenes area. In the regions of Hopelchen, Dzibalchen, and Iturbide are a number of remains varying considerably in size and importance. Those examined were Dsehkabtún, Nocuchich, Dzibilnocac, Nohcacab II (or IV), Chenchan (Chanchen), Tabasqueño, Dsibiltún, and Hochob. The last two are worthy of particular mention. Hochob, the southernmost point reached, offers a wealth of splendidly preserved architectural detail which, stylistically, is probably further removed from the decoration of the Puuc than is that of any other site visited. They may prove to be typical of the Chenes, or may be transitional to another school of architecture farther to the south. Dsibiltún, near the village of Komchen in the heart of the Chenes country, exhibits a form of architecture that appears not only to be entirely Puuc in tradition but of a highly developed and presumably late stage. If the above-suggested cultural and chronological associations are correct, the site is obviously of great importance.

Lastly, the reconnaissance included Edzná-Tixmucuy, some distance west of the Hopelchen-Dzibalchen region. While Edzná was probably one of the great cities of the Yucatán peninsula, it is unfortunately so ruinous that it offers few architectural data, although further exploration may remedy this defect. What could be gathered from a single structure indicated that the remains are more closely allied to the Xcalumkin-Puuc group than to the Chenes, and that they might quite possibly have influenced Puuc development. The chronological position at present assigned to Edzná rests more upon the relatively early dates of its stelae than upon its architecture, although the latter corroborates the inscriptions by appearing definitely earlier than the characteristic Puuc forms.

The work at Uxmal was largely confined to the smaller and lesser-known structures. Of outstanding importance is the existence of several buildings that in mode of construction or style of decoration seem surely to be allied to the remains of the Chenes. Two of these

give evidence of being demonstrably earlier than the structures known as the Casa del Gobernador and the Casa de las Tortugas, but in so far as the Gobernador and Tortuga probably are comparatively late examples of Puuc architecture, the determination of the relative chronological position of the Puuc and Chenes styles is not greatly aided. It is worthy to note, however, that should we subscribe to the rather common view that the Chenes remains antedate those of the Puuc, a long period of occupation is indicated for Uxmal.

In judging the progress of the survey, it seems that the architecture of the Puuc has now been sampled adequately and that activity in that region may for the present be discontinued. The work of the past season greatly enlarged the survey's horizon, in that for the first time a considerable number of ruins outside the Puuc were visited. As a result, local culture areas are now beginning to take shape. There are indications, moreover, of inter-influence between areas, and suggestions as to relative chronology. Thus, we find that the Chenes culture penetrated to Uxmal, while the Puuc tradition was carried to Dsibiltún. It is becoming increasingly clear that certain existing ideas in regard to conditions in the western part of the peninsula must be revised. The different architectural styles and the local culture that these styles reflect can no longer be thought of as sequent stages in the passage of a single cultural impulse from south to north, each stage marking an advance in time. On the contrary, they must be considered as products of several impulses that may have varied widely in point of origin. It is possible, in fact probable, that difference in origin, rather than difference in time, was the major factor in bringing about the observed variation in the character of the remains.

Problems relating to the course of future work have been clarified. In earlier years Edzná, Holactún-Xcalumkin, Oxkintok, and possibly Jaina, had been marked out as of strategic importance in the western Yucatán-Campeche area. To these must now be added Xtampak, and probably Dsibiltún. The reconnaissance of the Chenes, moreover, has demonstrated the need for its fuller investigation and for exploration in several adjacent regions. South of Hochob there is a strip of archaeologically little-known territory that lies between the area traversed by the past season's reconnaissance and that covered by the Division's several Campeche Expeditions [Chapters 15.1 and 15.2]. In so far as much of the architecture of southern Campeche and southwestern Quintana Roo seems allied to that of the Chenes, it is important that the remains of the intervening area be better known. The work at Xcalumkin and the brief visit to Edzná indicate that the ruins in western Campeche differ in style from those of the Chenes. The architecture of these western

sites is closely related to that of the Puuc and, in conjunction with several relatively early Initial Series dates, suggests that the region formed the avenue of approach for many of the basic traits of Puuc architecture. Almost no remains are known between Edzná and Xcalumkin, although ruins are reported by the natives. This is an area in which one may look forward with some confidence to the recovery of hieroglyphic material, and there is little doubt that further work here will amply justify itself. Nor should the southwestern extension of this coastal region be neglected. South of Edzná and Champotón, and west of the area covered by the Campeche Expeditions is a blank spot upon the archaeological map. And as the Edzná-Xcalumkin-Puuc complex does not seem to find direct derivation either from the Chenes, remains or from those of the Petén southwestern Campeche is the logical place to seek earlier links in that cultural chain. The region, moreover, appears to have included the ancient cacicazgo of Acalán-Tixchel [Chapter 9.9] the history of which-forms the subject of a monograph now in preparation by Messrs. Scholes and Roys, and Miss Adams, and it is not beyond hope that some connection may be established between the archaeological remains and the documentary records. This would obviously be of great importance for the reconstruction of Maya history.

2.4.

H.E.D. POLLOCK

Architectural Survey

YB 36:141–143, 1937

Dr. Pollock's activities in 1937 differed from those of earlier years (for previous reports of the Architectural Survey, see [Chapters 2.1, 2.2, 2.3] in that instead of collecting definitive data on the architectural remains of relatively limited areas, he made rapid reconnaissance of an extensive territory. At the same time, he was able to visit several sites under excavation and to observe others that had witnessed a certain amount of digging in past years.

The first part of the season was devoted to the Guatemala highlands, a region rapidly becoming more accessible to travel but which as yet is archaeologically little understood. Prior to this the lowland ruins of Quiriguá and Copán were visited, as well as San

Agustin Acasaguastlán and, the little known ruins of Papalguapa and Asunción Mitá.

The next group of remains investigated was that centering about the town of Santa Lucía Cozumalguapa, on the Pacific slope of the cordillera. The sites of El Baúl, El Castillo, Pantaleón, Bilbao, Aguna, Los Tarros, Palo Verde, San Andrés Osuna, and El Portal, the last near Antigua Guatemala, were seen during this trip.

The final and most extensive phase of the highland survey included examination of an unnamed mound group between Kilometers 65 and 66 on the road from Guatemala City to Tecpán, and the well-known ruins of Iximché. A stop in Chichicastenango allowed observation of the famous Rossbach Collection. On succeeding days the sites of Utatlán, Chiché, Joyabaj, Zacualpa, Comitancillo, San Pablo Jocopilas, San Pedro Jocopilas, Zacleu, and three sites in the vicinity of Aguacatán were visited. Lastly, Dr. Pollock with Dr. Kidder inspected the Lake Atitlán ruins of Chuitinamit, Pachiuak, Chukumuk, Xikomuk, and Pavocol.

The above trips necessitated frequent passage through Guatemala City, where it was possible to see the excavations being carried on at Kaminaljuyú and to study the collections in the Guatemala National Museum.

Dr. Pollock devoted the second part of the season to reconnaissance of ruins on the Pasión and Usumacinta Rivers in company with Messrs. Smith and Shook.

Starting from Uaxactún, where Dr. Pollock had opportunity to see the results of over 10 years of intensive excavation, the combined party moved southward to the ruins of Tikal, where four days were spent. This visit resulted in the discovery of a previously unreported group of remains located about 1 km north of the Great Plaza, two new sculptured stelae (19 and 20), a sculptured altar (VIII), five plain stelae, and six plain altars. According to Dr. Morley, Stela 19 and 20 record the dates 9.18.0.0.0 and 9.16.0.0.0, respectively, each date being declared as a Period Ending. Leaving Tikal the expedition continued southward, visiting Ixlú, Tayasal, and Chakantún, in the course of the journey to Subin Creek, a branch of the Pasión River.

The small ruin of Aguas Calientes was the first site reached on the Pasión. The following day the party visited an unreported site about 3 km east southeast of the settlement of La Florida on the left bank of the river. The ruins were given the name El Caribe, from a nearby arroyo of that name. Two sculptured stelae (1 and 2), a hieroglyphic step-stone, and a plain altar were here discovered. While the readings are as yet uncertain, Dr. Morley feels that Stela 1 and two probably were erected to commemorate the date 9.17.10.0.0. Next day

a second now site, situated some 4 km south of La Florida and given the name La Amelia, was examined. This yielded a sculptured stela and six step-stones, all carrying epigraphic texts that still await decipherment.

The little-known ruins of Altar de Sacrificios at the confluence of the Pasión and Salinas Rivers, which together form the Usumacinta, were next visited. Exploration here revealed five new sculptured stelae (8 to 12), two new sculptured altars (2 and 3), five plain altars, and the fragments of two doubtful stelae. While much of the hieroglyphic material on these monuments remains to be deciphered, it seems clear that Stela 12 records the Initial Series 9.4.10.0.0, a very early date for this region, and Stela 8 the Initial Series 9.9.15.0.0. It is also reasonably certain that Stelae 9, 10, and 11 record Initial Series dates.

The party continued downstream to the ruins of Yaxchilán, El Chilé, El Cayo, and Piedras Negras, at the latter site being most kindly entertained by the Pennsylvania University Museum expedition, now at work there. Lastly, four days were spent at Palenque.

The results of such rapid and far-flung reconnaissance will become most clearly evident in the course of future work. New problems are defined, old ones are clarified, a more intelligent, more efficient program is made possible. The Guatemalan highlands constitute a region of great archaeological complexity, in that they not only have witnessed a relatively long period of occupation but have been subjected, at certain times, to numerous outside influences and cross-currents of culture. Any considerable amount of excavation in an area so little understood should be preceded by wider and more thorough reconnaissance than that undertaken this year. It is wholly probable that one or two seasons of careful work of this sort would go far toward determining cultural boundaries, and sub-areas delimited by these boundaries with characteristic remains of each; and should also permit selection of strategic points for attack.

The Usumacinta region has long been known to abound in impressive archaeological remains. It is an area, however, that is extremely difficult of access and that, for some years to come, will probably be very expensive to explore. As in the highlands, further reconnaissance seems advisable, but even careful reconnaissance in the Usumacinta country is arduous and costly. A site of obvious importance is Altar de Sacrificios-El Pabellon at the junction of the Pasión and Salinas Rivers, streams that drain the eastern lowlands and the southern highlands respectively, and that almost surely were ancient highways of commerce. The site should thus have been a meeting place of cultural currents from the Guatemalan highlands, the Petén lowlands, and the Usumacinta region. Work at this site

might not only yield indications of movements of culture and material of value for chronological cross-checking, but would greatly facilitate further exploration of the region, the confluence of the Lacantún and Usumacinta Rivers being a point of special promise.

2.5.

H.E.D. POLLOCK

Architectural Survey of Yucatán

YB 39:265–267, 1940

Brief reports upon the purposes and progress of the Architectural Survey have appeared in earlier *Year Books* [Chapters 2.1, 2.2, 2.3, 2.4]. It has been pointed out that the so-called Puuc region of Yucatán saw the initial efforts of the survey, and by the close of the 1936 season it appeared that that area had been sampled adequately. During these years occasion had been taken also to reconnoiter the Chenes region to the south and to make brief trips into the Maxcanú, Hecelchakan, and Campeche districts to the west and southwest. These last-mentioned districts, although relatively populous and easily accessible, form an area that has been a notable blank spot on the archaeological map; yet the information gained by these trips suggested, not only that the region possessed numerous remains, but that these remains were closely allied to, if not merely a variant of, those of the Puuc. The three comparatively well known sites in the area, moreover, appeared in each case to be of strategic importance. With the survey of the Puuc ruins completed and the Chenes ruins sufficiently sampled to give a good idea of what was to be expected in that region; it seemed logical to extend the work to this western area that appeared to have so definite a bearing upon the architecture of the Puuc.

Preparatory to entering an area whose ruins were virtually unknown, it was deemed advisable to conduct some preliminary exploration. During the preceding winter (1939) two native laborers, trained in the work of the survey, were consequently sent to this region to locate and briefly describe new ruins. The results were even better than anticipated. At very small cost these men visited and reported upon some 25 previously unrecorded groups. The Architectural Survey was thus able to enter the field the following year with

a long list of partially explored sites, and with valuable and time-saving information on such matters as facilities of transportation, water supply, and living conditions.

The 1940 expedition consisted of Dr. Pollock and Mr. Shook. The broad plan of operation was to start at Maxcanú, the northern tip of the area to be covered, and to work southward along the Campeche rail road line; constantly striking eastward into the interior hill region and occasionally ranging westward onto the coastal plain. In an earlier year the ruins of Oxkintok, just outside of Maxcanú, had been briefly visited and marked as large and of strategic importance, an opinion that was confirmed in 1939 by the discovery of a lintel carrying the earliest Initial Series date (9.2.0.0.0) so far known in northern Yucatán. Work was therefore begun at that site and was continued for about one month, a large number of outlying groups and two small nearby sites being explored as well as the centrally located ruins.

The ruins of Oxkintok are characterized by two types of building that seem to represent different periods of occupation. What are assumed to be the remains of the earlier period are akin to certain southern Maya ruins in assemblage, style of architecture, details of construction, and the association of monuments with hieroglyphic inscriptions. The early Initial Series lintel mentioned above is *in situ* in a structure of this style of architecture. The second class of building, assumed to be later, is of typical Puuc tradition. In general, the earlier remains tend to cluster in the central part of the site, and the outlying groups and a certain number of structures near the center are for the most part in Puuc tradition. These explorations disclosed some notable examples of stone sculpture and a considerable body of hieroglyphic material as yet not studied.

The second part of the season's work, again amounting to about one month was concentrated in the Cumpich-Xculoc-Halal region east of the railroad station of Hecelchakan. Some 20 sites, varying widely in size and importance, were visited. Broadly speaking, the remains of the region are akin to the previously studied ruins in the savanna of Xcalumkin. They are very similar to the buildings of the Puuc but, in Dr. Pollock's opinion, are distinctive in a sufficient number of details to justify their being set apart from the ruins of that area. As at Oxkintok, a considerable amount of hieroglyphic material and stone sculpture was discovered, and in addition some fragmentary examples of wall fresco were found.

The third and last part of the 1940 season was devoted to exploration of the region along the railroad and east of the railroad between the towns of Pomuch and Hampolol. Here again some 20 sites were visited, and in the main it may be said that the remains are in

the same tradition as those of the area surveyed on the preceding trip. Possible exceptions are the ruins of Bakná, northeast of Boholá, where there appear to be traces of the early-style architecture of Oxkintok; and Acanmul, near Hampolol, where assemblage and relatively high proportion of pyramidal-type structures set the ruins off from those of the major part of the region. During the final week the site of Oxkintok was revisited to check up on certain matters considered important, and at the same time the ruins of Sihó, west of Halachá, were visited. These last ruins, while in certain respects akin to those east of the railroad, are in other ways distinct. Upon returning to Mérida, a brief visit was made to the long known, but so far inadequately studied, ruins of Acanceh and Mayapán. It should possibly be noted here that the Acanceh remains are strikingly similar to relatively early southern ruins.

The work of the past season has, been one more step in clarifying the cultural picture of northern Yucatán. Not only have a large number of ruins been examined in an area that was relatively unknown, but that area is found to have a concentration of remains comparable to that of the Puuc region. The main concentration appears to lie in the hill and savanna region east of the railroad, the railroad towns mostly old aboriginal settlements, forming the western border at the foot of the hills. The coastal plain west of the railroad gives evidence of a comparatively sparse aboriginal population. From the point of view of architecture, the area is extraordinarily homogeneous. As noted above, the remains are so closely akin to those of the Puuc as to present the question whether they should be differentiated at all. There is little that occurs in the region that might not be found in the Puuc; but Dr. Pollock believes that the proportion of certain forms of assemblage, types of buildings, ground plans, structural details, decoration, and glyphic material justifies distinguishing these remains from those of the Puuc. Departing from the general architectural homogeneity of the region are the presumably early remains of Oxkintok, which represent a cultural horizon that may be present at Bakná but as yet finds no direct parallel elsewhere. Acanmul and Sihó also give signs of difference from the norm. The source and cause of these divergences are at present unknown.

Future objectives of the Architectural Survey seem clearly to lie to the south in the region extending east from the Campeche-Champotón coastal strip. The work of the survey to date has given good indications of the borders of the Puuc and of this new subcultural area in its northern sector, but its southern limits have not been defined, nor has the expected Chenes border been discovered. An extension of the survey south and southeast should solve these problems. In addition,

there is hope of picking up further traces of the early Oxkintok architecture. In the past it has been the experience of the survey that major advances in the understanding of the broad cultural picture have come in passing from one cultural area to another, and it is confidently expected that the delimiting of this new area to the south and southeast, and the knowledge of what type of remains are contiguous, will greatly clarify the relation of these remains to those of the Puuc and Chenes. There are, moreover, the broader questions of the entrance and continuing flow of culture to Yucatán from the south and west, and the region suggested for future work appears to hold promise of throwing light upon such problems.

2.6.

H.E.D. POLLOCK

Architectural Survey of Yucatán

YB 45:206–207, 1946

Dr. Pollock returned to the Division in September 1945, following Army service of somewhat over three years. At the time of his departure in 1942, he was engaged in preparing for publication the results of field trips to Yucatán and Campeche beginning as far back as 1932. A résumé of the field work of the Architectural Survey with references to earlier reports appears in [Chapter 2.5].

On resumption of work with the Division, it seemed desirable that Dr. Pollock should spend some time in studying the very considerable amount of Middle American archaeological literature published during his absence. Several months were devoted to this pursuit, and the reward is probably to be measured equally in terms of reorientation of the worker and in knowledge gained of the advancement in research.

It has long been felt by Dr. Pollock that the publication of architectural data should rely mainly on illustration rather than text. The preparation of such material, consisting in the present instance of a great number of drawings as well as photographs, is a time-consuming process. A large amount had been prepared prior to his departure; but the hiatus of almost 4 years made necessary a thorough recheck to discover what details had been omitted, and to refresh the memory in regard to the general content and specific problems of the task in hand. This work is now in progress.

It is not wise to be rigid in establishing the precise form and content of a publication when the raw data are still in process of reduction to final form. Some thought may nevertheless be given to the problem. In the present instance, information that should some time ago have been available to fellow workers has yet to appear. Moreover, the freshness of the research, as expressed in the myriad details the researcher carries in mind but never reduces to paper, has dimmed. The wise course therefore would seem to be to bring forth as promptly as possible a publication presenting mainly the factual aspects of the field work, and not to delay publication by the preparation of elaborate comparative data. It may indeed be advisable to publish the material in successive parts dealing with sub-areas of the region covered by the survey. When this stock of facts that have sat on the shelf so long is made available to all, comparative studies should be commenced—studies that presumably will be furthered not only by the Division but by other interested workers.

2.7.

H.E.D. POLLOCK

Architectural Survey of Yucatán

YB 47:218–219, 1948

It was noted in a previous report on the Architectural Survey [Chapter 2.6 this volume] that the immediate task in hand was the preparation of the illustrative material that will form the body of the final report on this work. In the working over of the notes, sketches, and photographs that are the raw data of the survey, it was inevitable that certain gaps, certain loose ends, should become apparent. Some of the lacunae and uncertainties thus uncovered seemed sufficiently important to merit checking in the field. Dr. Pollock consequently spent March and part of April 1948 in Yucatán.

As a good proportion of the checking concerned the ruins of Uxmal, this site was used as a base. The work was greatly facilitated by the kindness of Sr. José A. Erosa Peniché, archaeologist of the National Institute of Anthropology and History, in offering the use of the Institute's living quarters at the ruins. Approximately three weeks were spent at Uxmal, during which time trips were made to the ruins of Huntichmul I,

Kiuic, and Xculoc. Dr. Pollock was so fortunate as to have company of Dr. Morley during a part of his stay at Uxmal.

Toward the end of March Mr. Shook joined Dr. Pollock in Mérida and the two visited the well known site of Mayapán for the purpose of checking the existing map of the ruins in order to determine the advisability of additional mapping.

The small but excellent regional museum in Campeche was visited next. As the new highway connecting Mérida and Campeche had recently been opened for traffic the opportunity was taken to traverse this road, which continues the old Mérida-Uxmal highway to the ruins of Kabah, thence to Bolonchen-Ticul, to Hopelchen, and westward to Campeche. A number of ruined sites were observed along the road the most notable being that marked by high, pyramidal structure which may be seen at a distance of 2 or 3 km north of the highway between Uxmal and Santa Elena. Mr. Shook is of the opinion that this structure is part of a large site that observed from the air while flying from Guatemala to Mérida. It is probable that these are the ruins of Xcoch, discovered over 100 years ago by John L. Stephens and, so far as is known, never revisited. Also worthy of mention is a group of remains, immediately west of Hopelchen, that have been cut through and in part demolished by the construction of the new highway.

The work of the Architectural Survey has been retarded by the administrative duties assumed by Dr. Pollock in 1947. The results of this research are not so publication as might have been expected at this time. Although the great task of drafting the illustrative material is virtually completed, this material and the photographs are not yet arranged in final form for publication. Only a small part of the text has been written. It is hoped that Dr. Pollock will be able to give more of his time to this work in the ensuing months.

2.8.

F. B. RICHARDSON

Study of Maya Sculpture

YB 37:156–159, 1938

In attack upon the problems of any archaeological area certain definite processes are indicated. First must come a preliminary stocktaking of remains, their general nature and their distribution. The second step should

be the chronological ranking of those remains, in order to determine the extent and the location of population at different periods, and also to make clear the trends of cultural change. For this chronological ranking one should select types of evidence, which most clearly reflect the passage of time.

In the Maya field the Initial Series dates supply the most obvious material for the establishment of sequences; and during the early years of Maya research they were relied upon almost exclusively. But while these inscriptions are of the greatest value as chronological landmarks, they cover a period of only about 500 years. They supply, therefore, no evidence regarding the obviously long developmental stage which preceded the erection of the earliest monuments; and Initial Series ceased to be recorded several centuries before the coming of the Spaniards. Furthermore, monuments are few or lacking at many sites even of the epoch of greatest inscripational activity; and none at all occur in the important peripheral districts.

For this reason it is necessary, in an attempt to deal with the whole area and the entire span of Maya history, to include intensive study of criteria other than epigraphic. Of these, pottery and the details of architecture are among the most useful and have been made the subject of special researches and surveys by the Division. Of almost, if not quite, equal importance is sculpture, an art in which the Maya were pre-eminent among the prehistoric peoples of America.

Maya buildings were lavishly decorated with carvings in stone and with figures modeled in stucco. The monuments bearing the above-mentioned hieroglyphic dates were also elaborately sculptured and, as Spinden demonstrated some years ago, it is possible by means of the dates on the stelae to establish the trends of sculptural technique. Conversely, the nature of their carving permits determination, in many cases, of the age of stelae whose inscriptions have become undecipherable through breakage or the erosion of time. The stylistic evidence offered by sculpture has therefore come to play a significant role in epigraphic as well as in architectural research. Furthermore, there are important linkages between sculpture, jade carving, and the decoration of pottery. Finally, Maya art formed an integral part of the larger art field of Middle America. It influenced, and was influenced by the work of other neighboring cultures.

The study of sculpture is thus of great importance; but the mass of sculptural and closely allied material is so great, and artistic and technical problems are so many, that epigraphers, ceramicists, and students of architecture must rely upon others for the highly specialized sculptural data they require. For this reason Mr. F. B. Richardson has undertaken a detailed survey of this aspect of Middle American culture.

The ultimate objective of Mr. Richardson's study is the comparison of Maya sculpture with similar developments in other parts of the world. Included among the immediate problems are: interrelation with adjoining cultures; identification of sculptural foci; tracing of trait diffusions within and without the Maya area; determination of the origin, the chronological development, and the influence upon the other arts of Maya sculpture. Such an investigation should contribute toward clarifying the history and society of the Maya.

The activities of Mr. Richardson, previous to the field season of 1938, were confined to the gathering of a comprehensive photographic file, and to examination of museum collections and the literature of the subject. During the winter of 1938, he made a rapid reconnaissance to the south and west of the Maya area, gathering data on regions which are archaeologically little known. The season's work was devoted to four districts: western Salvador, the Pacific area of Nicaragua, southwestern Honduras, and the central Pacific coast of Guatemala and the adjacent highlands.

In western Salvador, Mr. Richardson examined El Limón, El Congo, Las Siete Princesas, Casa Blanca, Quinta Elena, and Tazumal, all in the department of Santa Ana. In addition, he visited collections at Chalchuapa and Santa Ana, notably those of Sr. Carlos Álvarez L. and Sr. Luis Fredrico Mathies. En route from Guatemala City to Santa Ana and thence to San Salvador, he stopped at Asunción Mitá, noticed mounds near Plata and Los Esclavos in Guatemala, and at San Andrés in Salvador. In San Salvador he examined collections of the National Museum, of Dr. Oscar E. Salazar, Dr. Alfonso Quiñones, and Mr. Schmidt.

In Nicaragua, Mr. Richardson visited Asososca, Nejapa, Nindiri, Diriamba, Masaya, Masatepe, and Granada. The major part of the work, however, consisted of studying specimens in the collections of the National Museum, the Presidential Palace, Sr. David Sequeira, Dr. Joaquín Gómez, Doña Josefa Vde. de Aguierre, Mr. F. Bunge, Mr. R. E. Frizell, Mr. R. E. Harding, Mr. F. Dreyfus, Mr. Maurice Marragou, Mr. Alfred Bequillard, Mr. Morelock, Sr. José Maria Gutierrez, Sr. Constantino Marengo, Mr. Arthur Vaughan, and the Jesuit College.

En route from Nicaragua to Gracias, southwestern Honduras, Mr. Richardson stopped in Tegucigalpa to study and photograph material in the Honduras National Museum. From Gracias he rode down the valley of the Río Mejocote visiting the sites of Las Flores, Tapusuna, and Sehuatpeque. He then continued on to the valley of the Río Alash, reporting ruins at Cucuyagua and La Unión; the latter being fairly extensive and having been called to his attention by M. Rafael Girard through Dr. Jesús Maria Rodríguez,

Minister of Public Education of Honduras. In this same valley near the towns of El Corpus, Corquin, Sensenti, and San Marcos, sites were reported to, but not investigated by him. With Santa Rosa as a base, two unsuccessful days were spent trying to locate ruins reported by E. G. Squier in 1854, lying roughly about 16 km to the north of Santa Rosa. A subsequent three weeks' stay at Copán enabled Mr. Richardson to benefit from the accumulated results of many years work at that sculpturally richest of all ancient Maya cities. He also spent five days at Quiriguá, whose stelae are of outstanding artistic importance.

On the Pacific coast of Guatemala Mr. Richardson reconnoitered the lowland sites of Monte Alto and La Flora, El Baúl on the slope of the divide, and the highland sites of El Duranzo, El Naranjo, and Villanueva. From the lowland towns of Obero and Masagua, and the highland towns of Tecpán, Itzápa, El Tejar, and Antigua, sculptures not *in situ* were recorded. While in Guatemala City he studied collections at the National Museum.

The season's work necessitated frequent airplane travel allowing cursory geographical observation. In addition, reports gathered indicated unrecorded remains in areas surrounding those visited.

Such an extended itinerary opens up new vistas for future research and contributes toward a more adequate understanding of existing problems. The Pacific coast of Central America has long been recognized as a route of migration. Within this area in Guatemala, Salvador, Honduras, and Nicaragua, there appears to be a distinction between lowland and highland cultures. Certain traits are localized, while others cover a relatively large area. The Chorotegan sculpture of Nicaragua was found to have no close relationship to that of other known areas. Evidence gathered tends to weaken the hypothesis that the Chorotegan culture antedated that of the Maya. Certain sculptures from southern Veracruz, Tabasco, and northern Chiapas are believed to have affiliations with those of the Pacific coast of Guatemala. The Río Lempa in eastern Salvador apparently is close to the fusion point of northern and southern traits. In the department of Chontals, Nicaragua, remains differ from those of the lake region.

In Honduras, the archaeologically fertile and hitherto unexplored Alash River valley produced, among other sites, one with definite Maya traits in conjunction with surface material of non-Maya character.

Geographically and in part culturally the Guatemala highlands have much in common with western Salvador. The headwaters of the Río Alash interlock with those of the Río Lempa and together with the Río Mejocote they join to form the Río Jicatuyo. With the exception of the Comayagua Valley drainage, the Río

Jicatuyo is the largest tributary of the Ulúa River. It would therefore seem that further investigations in the western half of Salvador and in the Alash Valley should contribute toward a more adequate understanding of the Guatemala highlands and of the similarity between ceramic material from Salvador and that of northwestern Honduras. Under the Institution's present program Nicaragua lies too far afield for immediate additional attention. Further work on the Pacific coast of Guatemala should help to determine the geographical limits, chronological sequence, and routes of migration, of certain Middle American cultures. That area, accordingly, would seem most important for intensive study.

2.9.

TATIANA PROSKOURIAKOFF
A Study of Maya Sculpture

YB 45:209–211, 1946

A study of the development of monumental sculpture in the Maya area was originally undertaken with the object of resolving specific disagreements which had arisen as to the period of erection of monuments whose style was deemed by some observers to be incompatible with the dates inscribed on them. Although the results have not been in all cases decisive, the study has revealed the possibility of a clearer definition of the trends of artistic development in Maya sculpture than has yet been attempted. An exposition of these artistic changes is useful not only as an aid in establishing the chronological relation of monuments having no decipherable dates, but also in throwing light upon other aspects of culture and in revealing contacts between various sites and between the area as a whole and other regions of Mesoamerica.

The greater part of this year was spent in developing a convenient system of stylistic appraisal based on the duration of traits and qualities of design as determined by their known occurrences. A method was devised by which traits of a given monument can be compared with a standard illustrated series, which also shows on a time scale the periods of which the traits are characteristic. The time distributions of all the traits observed on the monument are then combined in a single graph which indicates the span of time in which the given combination of traits is most

likely to occur. This method is not intended to supplant the more discriminating judgment of experts who can sense variations that cannot be clearly defined. It has the advantage, however, of being less dependent on subjective reactions or preconceived theories of aesthetic evolution, and of demanding no specialized training on the part of the investigator who wishes to make an independent evaluation of the style of a given monument. It is hoped that it will bring into closer agreement opinions which are now widely divergent. The chief limitation of the method is that it rests entirely on the known epigraphic series, which is very unevenly distributed through the body of sculptural material. Close determination of stylistic affiliation, therefore, is possible only for stelae of the period of Initial Series and sculptures of similar type. When this method is tested against the epigraphic series by assigning to each of the 137 dated monuments an optimum date on the basis of its trait graph, the errors resulting are not greater than two katuns in about eight out of 10 determinations, and not more than three katuns in nine out of 10. Larger errors occur when the monument tested is of the early period, which, though of long duration, is scantily represented; when the carving is badly effaced; and sometimes when the design is atypical or poorly executed. In view of the differences in skill and taste of contemporary artists, the unequal distribution of dated material, and the erosion that mars most of the monuments, greater reliability of chronological estimate is perhaps not to be expected.

The illustrated series of traits, chronologically arranged, reveals that the important directions of change are related to purely aesthetic considerations. The traits which show most consistently progressive changes during the period of the Initial Series are those which may be defined as types of form configuration, and not those which are based on the choice of motif. The development, therefore, is most clearly demonstrated by a comparison of abstract decorative forms of similar structure. There appear to be two major periods, separated by a gap of nearly a century (9.4.10.0.0–9.8.15.0.0), which was singularly unproductive of any major sculptural work. The earlier period is too poorly represented to show trends of development, but as a whole may be characterized by distinctive positions of the human figure and by simple structure and configuration of decorative forms, frequently designed with stress on a vertical axis. For the later period, a definite progress can be traced in the study of forms and in their manipulation to produce aesthetic effects. The first sculptures of this period can be recognized by the survival of specific qualities of early arrangements combined with a more studied, but still simple, delineation. The direction of progress is toward more perfect

geometric regularity and more complex structure, in which previously independent elements are adapted and related to each other in arrangements which, though not directly copied from nature, resemble natural motifs in their logical organization. Curvilinear rather than axial arrangements predominate in this period, and rhythmic variations of curve and straight line are mathematically precise, as in the progressively diminishing undulations of waving forms, which in the earlier periods tend to be irregular. The latest phase of this development shows emphasis on expressive and mobile qualities of forms and their free adaptation to the purposes of the general composition. This results in irregularities due to deliberate distortion and exaggeration and culminates in a type of delineation that may be designated as cursive.

In Yucatán the aesthetic development is less consistent, and since there is little material which can be dated on the basis of inscriptions, the definition of trends and influences is more difficult. It is doubtful whether a chronological sequence of monuments in Yucatán can be constructed on the basis of style alone, since many variations, particularly of the later periods, appear to be fusions of different styles, and are dependent on historical juxtaposition of these styles. There is no reason to suppose that they would form in any sense a progressive series. Rare and scattered examples of sculpture closely analogous to that of the earlier phases of development in the south indicate that the progress may have been at first roughly parallel, but the fact that the latest phases cannot be identified in the north may mean that the influx of foreign influences in this area came before the end of the period covered by the Initial Series. The investigation at present is chiefly concerned with defining the qualities of the many schools of Yucatán sculpture and formulating the problems of their interrelation.

The Mexican school of Chichén Itzá, which was the last highly developed school in Yucatán, presents interesting opportunities for the study of an eclectic style. It is less preoccupied with the aesthetic effects of form than is the art of the southern area, and concerns itself primarily with the presentation of dramatic subjects, a quality which reflects the troubled spirit of the times. Some of the qualities and even the specific forms it employs are remarkably similar to those of the earliest Maya stela. Possibly this can be explained by the survival of these traits outside the Maya area and their reintroduction in late times. Similar qualities may be wed in some sculptures of the Puuc, and in very late monuments of the southern area. At Chichén Itzá, these apparently archaic traits are combined with others which are directly traceable to the style of Tula, Hidalgo, and still others which appear to stem directly from the tenth-cycle period of the Initial Series. The latter traits,

which have not yet been observed in the Puuc, suggest that a fusion of the Tula style with the local variant of the Puuc found at Chichén Itzá may not be sufficient in itself to account for the origin of late Chichén Itzá sculpture, though no explanation for the presence of these traits is yet apparent.

The problem of the interrelation of styles in Yucatán is very intricate, and a survey of monumental sculpture in this area must rest content with mere suggestions, for the amount of material available for study is relatively meager. The history of design as a whole, however, is probably closely paralleled in architectural ornament, in mural painting, and in pottery decoration and other minor arts. Each of these must contain developments peculiar to its own technique and subject; but they are at all times interrelated, and only detailed descriptive presentations and analytical studies of each of them will make possible a comprehensive study of the progress of artistic styles.

2.10.

TATIANA PROSKOURIAKOFF
Maya Sculpture

YB 46:189–190, 1947

The summer and early fall of 1946 were devoted to the preparation of the text which is to be an exposition of the results of researches in Maya sculpture carried on during several seasons. The study deals chiefly with general trends of development in the lowland Maya area as a whole, and these have been briefly summarized in a previous report. Their more detailed statement brings out certain points in regard to the regional distribution of traits which suggest changes in the degree of contact existing between separated sites of the Maya area at different periods of its history.

For the eighth cycle, the material is very meager, and it is not possible to give a clear description of the prevalent styles or their distribution. Strong similarities between Maya sculpture of this period and certain monuments which have been attributed to other cultures on the periphery of the Maya area may be significant. The carving on the Hunacab mouth of the Igo Cave of Loltún, the stela at El Baul which bears a disputed early date, the sculptures of Santa Margarita and San Isidro Piedra Parada in the Department of Quezaltenango, and certain monuments of Kaminaljuyú

exhibit traits characteristic of the earliest phase of the Early Classic period. Since the seventh-cycle and early eighth-cycle dates suggested by the inscriptions on some of these monuments fall outside the known range of Maya sculpture, stylistic comparison cannot be used to confirm them, but it may in some degree overcome the reluctance to assign these sculptures to an early horizon.

At the end of the Early Classic period (in the first quarter of the ninth cycle) the Maya style appears as an integrated and distinctive entity wherever sculptures of this period are found. This period is followed by a hiatus, and when sculptural activity is resumed, at about 9.8.6.0.0 or 9.9.0.0.0, sculpture shows marked regional differences. Copán retains many characteristics stemming apparently from early Petén, and its style is closely related to that of the Leyden Plate. The most advanced characteristics seem to appear first in the western half of the area and to the north, indicating that the impetus of the new development came from either of these two directions. As the Late Classic period progresses there is a rapid fusion of regional styles, and particularly a spread eastward of Usumacinta traits. Complexes of traits noted at the beginning of the period at Piedras Negras become common in Copán after 9.14.0.0.0. Another group of traits links the Usumacinta and specifically Yaxchilán with the Puuc area of Yucatán. Although such stylistic similarities do not in themselves demonstrate direct contact between sites, they furnish valuable leads for the study of the relations existing between diverse regions.

In the winter of 1947 the study was interrupted by a field trip to the highlands of Guatemala in connection with the survey of that area reported by A. L. Smith. It was resumed in May, when we were very glad to acquire the services of Miss Kisa Noguchi in the preparation of illustrations which will be the basis of the method of stylistic appraisal proposed in the study.

2.11.

TATIANA PROSKOURIAKOFF

Middle American Art

YB 49:200–202, 1950

A monograph entitled *A Study of Classic Maya Sculpture* was completed and submitted for publication in December 1949. This study outlines sequent stages in

the development of ornamental forms on Maya stelae, for which scroll or volute forms furnish the clearest illustration. No attempt is made to compare this development with others outside the Maya area, since no sequences of artistic change have yet been worked out for other styles. Tracing the history of art is extremely difficult where there is no accurate method of dating monuments. At seemed worth while, however, at this time to make, as a sequel to the study of Maya sculpture, a cursory review of art forms in Mexico, and more particularly to explore the possibility of using our knowledge of the sequences of pottery wares to follow the development of those sculptural styles whose ornamental forms are reflected in pottery decoration.

A working catalogue of Middle American sculpture outside the Maya area was begun, and an attempt was made at a preliminary definition of styles, with particular reference to abstract ornament. The style formerly called Totonac, more recently Tajín or Tajínoid, is one of the most distinctive and ornate in Mexico. It seems to have had a wide influence and offers the best promise of showing a sequence of development as complete as that of the Maya style, if at least some of its variations can be correlated with pottery types and their stratigraphy. Its copious use of scroll forms, which in the Maya style proved to be sensitive to general artistic trends, makes it especially well suited for such study.

In February 1950 Miss Proskouriakoff made a trip to Mexico to look over pottery collections and to judge if their known sequences might provide clues to chronologically important changes in scroll designs of Tajín type. The stage of archaeological research in Mexico at present appears to be only a little short of making such an approach to art history extremely rewarding. An excellent stratified collection of pottery from Cempoalla, now being studied by Dr. J. García Payón, should yield valuable design sequences. Unfortunately, most of the decorated wares in this collection and others from Veracruz seem to be concentrated in late, probably Post-classic, periods. Gulf Coast designs, however, also occur at Teotihuacán, apparently as an intrusive trait, and there should be an excellent opportunity to correlate them with stratigraphy once the full range of stylistic phases at this site has been worked out. Recent archaeological work has uncovered stratigraphic sequences which are still being studied. Although at present there is considerable difference of opinion concerning the chronology of Teotihuacán remains, we may hope for an early solution to some of the major problems.

While in Mexico, Miss Proskouriakoff made a short trip to Tajín, primarily to obtain photographs of sculptured columns, which have never been adequately published. Tajín sculpture is the only con-

siderable body of material in Mexico which seems to show a connection with the Late Classic period of Maya art and at the same time depicts motifs similar to some found at Chichén Itzá. It is therefore of peculiar interest to students of the Maya. Moreover, Tajín architecture, though different in construction from that of the Maya, is at least as advanced in structural principle and also offers interesting stylistic parallels. It is possible that the sequence of development in Veracruz, when adequately studied, will provide a correlation with the Late Classic Maya period, which we still lack in central Mexico, perhaps because it was there a period of violent cultural change reflected in such events as the apparent destruction of the great city of Teotihuacán.

An attempt to sketch a history of artistic styles in Mexico would probably have little chance of success until archaeological work there is somewhat further advanced. Nevertheless, a definition of the variant forms of one motif, such as the scroll, including their occurrence in defined pottery complexes, may help to clarify some of the problems that need to be solved. A short paper discussing the types of scroll designs in Middle America and suggesting their possible interrelations is now being prepared.

2.12.

TATIANA PROSKOURIAKOFF

Art and Artifacts

YB 57: 451, 1958

To check on some questions that had arisen in the course of preparing a report on the artifacts of Mayapán, Proskouriakoff spent two weeks in Novem-

ber in Mérida. At the same time, 50 new specimens from Chichén Itzá and the Puuc region were catalogued, and the Mérida copy of the catalogue was checked and arranged for consignment to the Instituto Nacional de Antropología e Historia of Mexico.

The following two weeks were devoted to the examination of ceramic collections in the Museo Nacional de Arqueología y Etnología in Guatemala City, with the object of appraising their relevance to a projected study of the evolution of art forms in Middle America. The collections are admirably organized and include a large body of material representing sequent stages of development in highland Guatemala before the Classic Period of Maya art. The sequences have been worked out by Kidder and Shook in their collaborative work on the archaeology of the region, but only a very small part of the material has been published. From the earliest stages represented, the pottery is richly decorated and continuities in motifs and in formal treatment can be traced over considerable spans of time. Although it is not yet clear on what basis more or less independent traditions of ornament can be distinguished, it was observed that a small number of early wares employ designs that are clearly related to basic motifs of Classic Maya art. It is therefore possible that an exposition of continuities in developing traditions will draw definite limits to the degree and nature of artistic influences that can be ascribed to outside sources, and thus may restrict the field of speculation concerning similarities found in widely separated styles such, for example, as have been adduced in support of the hypothesis of trans-Pacific contacts.

In addition to opening possibilities of tracing back the history of Classic motifs, the Preclassic collections, because of the restricted range of the designs and their relative simplicity, present a body of material peculiarly adapted for testing various methods of describing and representing the changes that take place in a complex of decorative styles as the culture passes through successive phases of development.

3.1.

F. W. GAIGE

*Research in the Biology of the Maya Area
conducted by the Museum of Zoology of
University of Michigan in cooperation
with Carnegie Institution of Washington*

YB 30:128–131, 1931

So little is known, relatively, about the biology of Central America that a considerable amount of exploration will be necessary from the first to determine the species of animals and plants to be found in each biotic province and the relative abundance of the forms involved. At present the composition of the fauna and flora is inadequately known, while the distributional ranges of species is most vague. Data of this sort are of fundamental nature for more advanced studies in animal and plant biology; such knowledge is essential to any understanding of the history of the evolution and migrations of the faunas and floras in the area. Central America has served as a passageway for many North American groups of plants and animals to enter South America and for some South American groups to reach North America. Biogeographically, then, the region is a most significant and important

district. The present fauna and flora are a complex and little understood mixture of North and South American elements.

Explorations and biological reconnaissances over the region must be made, the data and specimens studied both for the area directly involved and in comparison with contiguous regions. The results can not fail to be of importance and real significance.

Much attention and study must be given to the ecologic relationships of the various animal and plant species, and the major ecologic communities will have to be determined for each of the biotic provinces considered. A knowledge of the influence of types of cover, that is, jungle, temperate forest, savannah, etc., the availability of water, and the many other environmental factors on the occurrences of the various species is highly important. The periodic changes in the abundance of

certain species, a common phenomenon in arctic and temperate regions, should be investigated for the tropics and where found given detailed study. The ecology of Central America is almost unknown. Certain biologists have expressed doubt as to whether ecologic communities comparable to those of the temperate regions can be found in tropical jungles, or at least distinguished as such. This is a fruitful field of investigation which can be profitably undertaken in a coordinated and continuous program with assurance of a solution. Studies of this sort can be adequately carried on where permanent field headquarters allow the concentration and protection of the necessary apparatus throughout the year.

Surprisingly little is known of the life histories and habits of the animals of the region. Even the major forms, such as the birds and mammals, present a great number of problems of the highest interest, while the smaller ones, insects, shells and various other invertebrates present almost endless lines of research. Some of these animals will undoubtedly be found to be reservoirs or carriers of tropical diseases of importance to man and animals, some of importance, harmful or beneficial, to agriculture. Studies in embryology, breeding, and nesting habits, periods of incubation, methods of life in all phases must be made and will supply new data on forms and to regions previously little known and understood. In connection with the studies on parasites and diseases which are carried by certain animals, special attention must be given to determination of the distribution, abundance and ecology of the species serving as secondary hosts or carriers.

Of high scientific importance will be the determination of the occurrence and effectiveness of the adaptations in the various species of animals and plants to the environment under which they live. Numerous presumed adaptations have been described and suggested for many tropical organisms, but little actual information is available as to whether these and other characters of structure and behavior are of real advantage to the species in its environment. Detailed experimental work is most desirable in connection with problems here.

Another problem of high importance for study in the field is that of the ability of various species, including man, to become acclimated to tropical environments. A knowledge of the factors in the environment which are responsible for the difficulty which the white race encounters in attempting to maintain itself in the tropics would be of great use. Some light may well be thrown on this relationship by observation of some of the species of lower animals and by carefully controlled experimentation with them. Here again are problems which could well be attacked with the facilities afforded by the permanent and adequate field headquarters available.

One of the important objectives of the biological work will be to determine the relationships which primitive man had with the native plants and animals and his effect upon them. The interpretation of data collected will fall upon both archaeologist and biologist alike and be of the highest use to each. From the standpoint of the animals, many were used as food, many destroyed food, some may have been of religious and ceremonial significance. What part the occurrence of ticks, mosquitoes, red bugs, sand flies and others may have had on a great aboriginal population needs detailed investigations. The numerous species of animals had become involved in the folklore of the Maya, and in elucidating the beliefs and history of this civilization and knowledge of the occurrence and habits of the species is important.

The identification of the many animals used by the Maya in his sculpture will be greatly aided by an understanding of the present fauna. In 1910, Tozzer and Allen made an admirable preliminary report of phases of this field of investigation. The collection and preparation of skeletons of the birds, reptiles and mammals and their identification will be of great use in the determination of such fragments as are found in excavating the ruins and other sites. Without such check material, serious errors can be most easily made in interpretation of both carved figures and skeletal remains.

From the botanical side, of special interest in connection with the archaeological work will be the search of the plant cover of the ruins for economic plants which may be interpreted as vestiges of ancient cultivation. Only long experience can show what plants really belong in this category. The shrubby *Physalis* of the ruins of Uaxactún and the *Agave* of the great temples of Tikal must be suspected as such. The aguadas, too, are likely to yield plants not truly indigenous but which owe their distribution to human agency. One must not overlook the possibilities among the plants of the jungle, but here the problem is so complex that only wide travel and long experience in the region will enable one to judge what in the present distribution of plants is natural and what has followed human occupation of the land. Here again the ethnobotanical problems merge in into those of phytography and ecology.

One can not undertake exploration of a complicated vegetational area, such as that of the Maya, with any hope of solving quickly the major ecological problems presented by the ecological succession from artificial clearing to old jungle. It will be necessary first to do a great deal of purely descriptive work, covering the area by intensive study at as many points as possible and connecting these points by rapid traverses. In the long run the data accumulated by a thorough going biological survey will throw light upon the

former utilization of the area by man, but it would be futile indeed to attempt to draw any conclusions until a basis had been established by detailed analysis and mapping of the fauna and flora. There is as yet no criterion for a judgment as to what is primeval forest and what is secondary in the sense it has followed human occupation. From the botanical standpoint there must be statistical analyses of the flora, 1. with especial reference to the relative abundance of non-economic plants with heavy seeds, as contrasted with those spread rapidly by wind; 2. of species intolerant of shade as contrasted with those shade-tolerant species; 3. of species that appear to be outside of their natural phyto-geographic boundaries as contrasted with undoubted natives; and 4. of species that might have been protected because of economic or ceremonial importance. Effort must be made to accumulate a Maya vocabulary of plant and animal names, checked against proper determination of the specimens.

With this brief summary of some of the avenues of research which are wide open to biological investigation in the Maya area and which would yield results of sound scientific and economic value, it seems desirable to outline the work of the biologists for the past season at Uaxactún and adjoining regions.

Three men participated, Dr. J. Van Tyne, Dr. A. Murie of the Museum of Zoology, and Professor H. H. Bartlett of Department of Botany. The first was responsible for the bird studies, the second for the mammals, the third collected plants for the University herbarium. In addition to their particular interests, the men took certain other material, Dr. Van Tyne and Dr. Murie collected reptiles and amphibian, fish, crustaceans and insects for the Museum of Zoology, and Professor Bartlett made a collection of spiders for Professor Chickering.

Due to prolonged rains, the party spent the first part of the field season, January 26 to middle March, in a careful investigation of the fauna and flora of the "pine ridges" in British Honduras near the Guatemalan frontier, the trail into Uaxactún being impassable. The study of the plants and animals of this isolated ridge above the jungle was most profitable and will prove still more valuable when similar work is done on the ridges of the Petén. The effects of both isolation and elevation can be splendidly observed on the ridges, and the effects on the fauna and flora seen.

Some work was also carried on along the upper reaches of the Belize River in British Honduras to furnish check material for that accumulated in the Petén.

About the middle of March the trail into the Institution's field headquarters at Uaxactún became passable and the party moved there to establish a base for work in the jungle of the Petén. Professor Bartlett left there about May 1 and the others about May 17.

The season was highly successful in all ways. Some 900 specimens, skins and skeletons, of birds were taken, 720 mammals, skins and skeletons, many specimens of other animals as noted before, and 3,000 collections of plants. Many hundreds of photographs were taken of living specimens, ecologic associations, and items best recorded for final reports by photography.

The expedition was assisted in this season's work by a grant from the Carnegie Institution of Washington and by the use of the Institution's facilities in British Honduras and Guatemala.

As this report is written in June the men are just in from the field, the collections not unpacked and data in field form. Work will start immediately on reports of the season's results, and it is expected that within the year they will be ready for publication. It is felt by the Museum of Zoology that in a cooperative enterprise such as this, results must be made available to cooperators as rapidly as practicable in order to be of full use.

3.2.

ALFRED V. KIDDER

Geographical Research in Guatemala

YB 31:101-107, 1932

Knowledge of the structure of the land and of its possibilities of its use by man, together with information upon how modern populations avail themselves of its resources, in other words, materials of the sort gathered and recorded by geographers, is essential both for an understanding of present-day life and for interpreting the necessarily meager and purely factual record compiled by the documentary historian and the archaeologist. The special methods developed by geographers for the collection of data and for analyzing the complex interrelation between human beings and their physical and biological environments, should unquestionably be called into service in any such survey as that of the Maya area. Geographical research was accordingly begun during the winter of 1932 by Dr. Wallace W. Atwood, President of Clark University, who generously donated both his services and the expenses of his expedition; and by his son, Dr. Rollin S. Atwood of the University of Florida, the University cooperating most effectively by granting Dr. Atwood leave on salary during the period of the investigation, Carnegie Institution providing the funds for the research.

The Atwoods, with Mr. Webster McBryde, a graduate student of Clark University, took the field in February. The highlands of Guatemala were chosen as the scene of the first year's work. Several considerations dictated the choice of this region. Most cogent was the fact that large Indian populations are still living there in more nearly their aboriginal condition than in any other part of the Maya area. Also, the region is most important archaeologically, having been the seat of high cultures in late prehistoric times; as well as the probable home of the early peoples who are believed to have contributed elements to the very foundation of Maya civilization. Furthermore, the country is healthy and readily accessible; several other investigations are going forward there. Last, but by no means least, the government of Guatemala and its president, General Ubico, have been most helpful and cooperative in forwarding the Institution's scientific activities.

Dr. Wallace W. Atwood undertook the definition of the physiographic provinces of the central highlands, with special attention to study of Lake Atitlán and the territory immediately adjoining.

The most striking feature of the highlands is the chain of recent, and in cases active, volcanic cones which borders the region on the southwest. Many of the peaks rise to over 11,000 feet [3,350 m]. They are but lightly etched by running water and for the most part are clothed with forests to within a few hundred feet of the summits. Most of the highlands under consideration are of volcanic origin, and by far the greater bulk of the material composing them is of fragmental nature. One explosive eruption followed another throwing ashes and dust high into the air. This material settled slowly and accumulated over the entire landscape. At several localities volcanic ash at least 3,000 feet [914 m] in thickness can be examined. Most of this material is of pumiceous character. Relatively few flows of heavy lava were noted. The huge cones are chiefly of basaltic flows, but the materials which compose the inhabited portions of the highlands are pyroclastic in origin. Thus the volcanoes that are conspicuous in the topography of today must be conspicuous in any analysis of the origin of land forms in this part of the Republic.

Related in origin to the volcanic peaks are the modern ash basins, large flat areas of pumiceous ash fallen, for the most part, from the air, but also supplemented by intercalated and bordering deposits washed from adjacent slopes during and since the period of maximum volcanism. This ash lies in what appear to be old, relatively deeply eroded basins, filling them to an almost uniform level. Examples of such basins are the region of Guatemala City, that of Chimaltenango, the area between Chichicastenango and Santa Cruz Quiché, the vicinity of Quezaltenango.

Although he was unable to visit them, Dr. Atwood believes, from inspection of the relief map at Guatemala City, that there may well be others in the region of Salamá, and another centering, at Cubulco. The flat or gently undulating surface of the modern ash basins, and their fertile soil, have naturally made them focal points for agricultural communities where large populations can be sustained. The deep-out gorges or barrancas, whose almost vertical walls testify to the recency of their origin and therefore to the youth of the deposits which they dissect, are eating rapidly into the basins, and threaten seriously to reduce the area of farming land.

Bordering each of the modern ash basins studied are older ash deposits which are in a much later physiographic stage of development. Their topography is so rough that it should be described as mountainous. There are evidences of at least two cycles of erosion. During the first cycle a late stage of maturity was reached. Broad, open U-shaped valleys were developed. In the younger cycle, sharp inner canyons or gorges have been cut. These younger canyons or barrancas are now working headward and may be seen just below the upper U-shaped valleys in many of the mountainous regions. The older valleys of the first cycle or erosion are usually well cultivated. Drainage from them at many places falls or tumbles into the younger canyons.

Depth of weathering is greater and soil formation is much better in these provinces than in those that have been designated as modern ash basins: In many places, and notably along the road east of Los Encuentros, the black humus extends 8–10 feet below the surface. These rich soils have been discovered by the native Indian peoples of the highlands and many areas are under cultivation. Even the steep valley slopes have been cleared of their forest growth and planted each year for the production of corn and wheat. After a period of years the native people abandon a field which has been under cultivation and allow the forest growth to return, so that the landscape is distinctly patchy or spotted, cultivated fields alternating with forested areas. In many instances the cultivation is continued to the watersheds or divides, and this has resulted in considerable, destructive erosion. In other places, the timber have been allowed to remain, and in the region of Chichoy hill there is a magnificent forest which appears never to have been completely removed.

The large communities or villages are not located in these older areas of ash deposits. The landscape is dotted with little-thatched roof cabins where the native people make their homes. They live near their fields and have the custom of going each week to market in some neighboring village.

THE ANCIENT CRYSTALLINE AND METAMORPHIC AREA

In the political province known as Totonicapán and northward into the political province of Huehuetenango, Dr. Atwood identified sufficient exposures to demonstrate the presence of a much more ancient geologic foundation than had been found in any of the other areas studied during the past season. In this physiographic region there are deeply weathered granites, various micaceous schists, quartzites, conglomerates, ancient coarse-grained volcanic breccias, and various types of ancient lava flow. Structurally this region has the character of an ancient massif, and yet there is in many places a mantle of relatively recent volcanic ash. This most ancient of the physiographic provinces thus far defined probably extends far to the northward and westward of the route along which it was examined. East and northeast of Guatemala City along the route of the railroad to Puerto Barrios there are exposures in ancient metamorphic rocks, lava flows and breccias that indicate that the topography in that region, preceding the relatively recent and violent volcanic activities in the highlands of Guatemala was much more rough or mountainous than it is today. That area was not seen in sufficient detail to be classified as a physiographic province, but from travel along the railroad the hypothesis was formulated of an ancient mountain area of complex structure and metamorphosed rocks in which the elevations were buried up to their shoulders in volcanic ash.

RECENT ALLUVIUM

In the highlands of Guatemala the extent of recent alluvial deposits is very slight. This is a region of extreme youth from a physiographic standpoint. The streams have not had time in the present cycle of erosion to develop broad flood plains. There are a few small deltas and torrential fans about the shores of Lake Atitlán. They have been discovered and pressed into use by the native people who are always on the search for more good lands where food may be produced. About the shores of Lake Atitlán and southward along the outlet drainage from that lake there is a little alluvium. When physiographic studies are extended into some of the old parts of Guatemala and into the coastal lowland bordering the Pacific Ocean, much larger areas of alluvium will be discovered.

LAKE ATITLÁN

Dr. Atwood devoted special attention to Lake Atitlán which, he believes, is a great crater lake or, most properly speaking, a caldera. If so, its rim-to-rim diameter

of some 12 miles [19.3 km] makes it one of the largest, if not the largest, in the world. Evidence in support of the caldera hypothesis is furnished by the vertical, faulted faces of the spurs between the valleys cut into the walls for the basin; by the outward dip of lava flows and ash beds in the wall; and by the uniformly great depth of water (1,000–1,100 feet; 300–335 m). The volcanoes Toliman and San Pedro, which tower some 6,000 feet [1,820 m] above the lake's surface, are, in Dr. Atwood's opinion, of much more recent origin than the caldera.

Within the great caldera occupied now by Lake Atitlán there are no less than nine Indian villages that are situated but a few feet above the water level. Within the present drainage area and located 1,000 to 2,000 feet [300–600 m] above the waters of the lake there are six others. The native people have chosen the deltas and the torrential fans for their settlements in some instances, but in at least two they have placed their homes in order not to invade the agriculturally precious alluvium, upon lava flows and have built their houses of blocks of basaltic lava. The many ruins observed by Dr. Lothrop testify to a dense aboriginal population.

In closing his preliminary report, of which the preceding paragraphs are a skeleton summary, Dr. Wallace W. Atwood expresses the opinion that Guatemala offers to the physiographer a most fertile and important field.

Dr. Rollin S. Atwood had as objectives for the season: to size up the geographic problems of the highlands as basis for a definite program of future activities; and to undertake a detailed geographic survey of a typical area. The region of Chichicastenango was selected for the intensive study, headquarters being made at the residence of Padre I. H. Rossbach, the representative of the Catholic Church at that city, a gentleman whose hospitality, scholarship and unfailing helpfulness have done so much to facilitate and to render pleasant the work of all scientists who visit his parish.

The town of Chichicastenango with, its adjacent villages has a population of about 30,000, composed almost exclusively of Indians who maintain to a remarkable degree their native individuality. It lies near the center of one of the great ash basins described by Dr. W. W. Atwood. The preliminary examination of the region gave the impression that the population is more or less evenly distributed. A more careful study, however, showed that all the large present-day villages and, in most cases, even the small settlements are located in direct relation to the physiographic features which control the water supply. It also became apparent that changes in the water table have resulted in abandonment of certain areas occupied in ancient times.

The foundation of all life and work in the highlands of Guatemala is agriculture. In the Chichicastenango basin it is predominantly the growing of corn, wheat, and beans. Wheat, due to its ability to withstand lower temperatures, is grown in the "high cantones" on the maturely dissected rim of the basin. Corn holds full sway throughout the inner basin, but because of the universal demand for it and the enticingly rich soils of the higher, colder and rougher regions, is also cultivated on the rim. The planting near Chichicastenango takes place after the second heavy rain, which usually comes about the middle of May. Cultivating is done about every six or eight weeks throughout the rainy season, which lasts until about the middle of October. In November the "*puntas*," sections of stalk above the ears, are cut off to stop further growth; and the ears are allowed to ripen and dry out until the middle of December, when they are harvested. During the entire growing season the Indians carry on more or less elaborate religious ceremonies.

Although practically every Indian in this region is engaged in agriculture, there are scarcely any who work solely on their land the year around. Out of a total population of approximately 30,000, it is estimated that slightly less than 8 percent do part time work on the coffee and sugar fincas near the coast. Almost all adult male Indians who do not work on fincas engage to some extent in commerce. A few of the less energetic are satisfied with carrying their 75 to 90 pound loads of produce each week to the local market of Chichicastenango. For many of these, this means a long journey over narrow and steep mountain trails. The large majority, however, not content with doing merely local business, travel on foot from one market to the next, selling and buying at each one. Thus there is produced a network of trade which covers the entire Republic and extends far beyond its borders. The careful tracing out of this commerce is essential for understanding the social and economic life of the highlands. Its roots, too, doubtless go back to prehistoric trade. Dr. Atwood studied the markets of the several towns visited, noting the major products bought and sold in each. He made a very detailed investigation of the market of Chichicastenango.

In the Chichicastenango region, industrial development, as it is known in the United States, is entirely lacking. Manufacturing is in the early handicraft stage and is practically limited to products used by the Indians themselves. Detailed descriptions of the major industries were recorded and an economic and industrial survey of the town itself was made.

Both Dr. W. W. and Dr. R. S. Atwood report that the lack of a good topographic map of Guatemala greatly handicaps all geographical work. They stress the fact that the detailed observations necessary for solving

the geological and physiographic problems of the Republic cannot well be made, nor can data from different regions be correlated without maps far more accurate and upon larger scales than any which now exist. And the essential investigations in human geography: the studies, for example, of soil utilization, of distribution of crops, of land ownership and of village boundaries, also urgently require adequate maps to serve, at least, as the basis for sketch enlargements to be made in the field. The Guatemalan government is not at present able to undertake the necessary surveys, but its enlightened attitude toward all scientific activities renders it probable that every possible aid would be given. Attempt is therefore being made to bring about this badly needed and, intrinsically, very interesting cartographic project.

Mr. McBryde's work consisted of an intensive study of Sololá, a thriving Indian community perched far above Lake Atitlán on the rim of the great caldera. He prepared a traverse map of the town and immediately surrounding country, showing physical features, such as hills and streams; and cultural features, streets and roads, ditches, aqueducts, buildings of all sorts. For the central part of the town was recorded the distribution of stores, administration buildings, churches, residences, etc. The map also indicates the use of non-urban land, showing crop distribution, pasture and forest. Notes were taken upon crops, growing seasons, agricultural methods, political organization, industries, religious ceremonies in relation to planting, to harvest and to market; upon artisans—the distribution of their shops, and where, generally, they learned their trades. He collected climatological data, census material, and made a complete photographic record.

To the market Mr. McBryde, like Dr. Rollin Atwood, paid special attention. He listed all commodities sold, with names in Spanish, Cakchiquel, Quiché and Tzutujil, and prices. On four weekly market days he gathered, with the help of native assistants, a detailed record of all Indians entering Sololá, of their provenience, and of their loads both coming and going. This record is supplemented by a map of the market place locating every vendor by sex, town of origin and commodity sold.

3.3.

C. L. LUNDELL AND L. C. STUART
Botanical-Herpetological Survey

YB 32:108–111, 1933

The biological survey of the Maya area under the joint auspices of University of Michigan and Carnegie Institution was forwarded by studies made between March 28 and June 12, 1933, in the savanna country near La Libertad, Department of the Petén, Guatemala. The expedition was in charge of Mr. C. L. Lundell, botanist; Dr. L. C. Stuart served as herpetologist. Its purpose was to explore the area and make a preliminary biological and geographical survey. There was collected a total of 2,800 plants and more than 10,000 herbarium specimens, together with ecological data and information regarding vernacular names and native uses of the plants. Plant associations were carefully studied, and every collection was made according to habitat. All of the plant associations were photographed. Frequency indices were made to show the distribution of species in the various ecological areas. Dr. Stuart took soil samples from every area, and Mr. Lundell gathered geological data which will aid in defining the vegetational zones.

In spite of the fires which swept the bush and open areas, it was possible to obtain a representative collection of the dry-season flora of the western portion of the Petén savanna country. As this work represents the first extensive plant study made in the region, the collections are of great scientific interest. Many of the plants are new, and in some groups as many as 10 percent are probably new species. Emphasis was placed on groups least known from the Maya area. Extensive collections were made of mosses, ferns and the epiphytes which include orchids and numerous species of the pineapple family. Some interesting new palms were found and adequate herbarium material was obtained, so that this group can be critically studied. Especial attention was given to trees, and some interesting new species were discovered.

The flora of the savanna country varies considerably from that of the Yucatán peninsula. The area may be considered as the transition zone between the floras of Yucatán and the region to the south. The line where the Yucatán flora terminates may roughly be drawn across the base of the peninsula from Laguna Perdida to Lake Petén and then to the Belize River in British Honduras.

The savanna country may be considered as a definite phytogeographical division. It is apparently the bed of a great ancient lake. The region consists of wide

open areas of red clay of great depth broken by low ranges of forested limestone hills. As the open clay country is very fertile, it was probably cultivated extensively by the ancient Maya. This cultivation and the seasonal fires accompanying it may account for the present open savanna areas. The flora is essentially that of species adjusted to annual fires. Bush is encroaching in every direction, and if there should be a period of wet years without fire, there is every likelihood that the entire region would be reclaimed by forest. Studies were made of the forest species which appear to be reclaiming the open country.

The ethnobotanical work included a study of the food and fruit plants now found in central Petén. Many of these plants were important in the economic life of the ancient Maya. Mr. Lundell's earlier studies on Maya agriculture and the milpa system were continued.

The ethnobotanical work included a study of the food and fruit plants now found in central Petén. Many of these plants were important in the economic life of the ancient Maya. Mr. Lundell's earlier studies on Maya agriculture and the milpa system were continued.

3.4.

R. A. EMERSON, AND J. H. KEMPTON
Agronomic Investigations in Yucatán

YB 34:138–142, 1935

Studies of modern Maya diet made by Dr. Steggerda, Dr. Redfield and Dr. Rollin Atwood indicate that maize forms some 85 percent of all food consumed. And, as would naturally be expected, the whole existence of the Maya is conditioned by the cultivation of this plant. There is also every reason to suppose that it played a role of equal, or even greater, significance in pre-Columbian times. Understanding of the present and interpretation of the events of the past therefore depends very largely upon knowledge of maize-growing methods and of the potentialities of the area for maize production.

The Maya of Yucatán cultivate maize by the so-called milpa system, under which an area of forest sufficient for the farmer's needs is felled at the beginning of the dry season. Toward the end of the dry season the desiccated slash is burned, and when the rains come the seed is planted. If all goes well, the first year's crop will be a good one; in the second year the return

will be less. Further consecutive sowing of the same field is seldom attempted; it is allowed to revert to bush and a new patch is cleared. This type of farming obviously requires a great deal of land, because the old milpa is not used again until forest conditions have become re-established. As this is a slow process, a large percentage of all available ground must at any given time be lying fallow.

One of the most vitally important of problems of Maya archaeology is whether the milpa system was followed by the prehistoric people of northern Yucatán and of the Petén, or whether some form of intensive agriculture was practiced. Upon its solution depends judgment as to the size and distribution of population, as to ancient economic and social systems, and as to the causes for the decline of the Old Empire. But until we know much more about the working of the present-day milpa system, we can not hope to do more than guess regarding its antiquity, nor more than speculate as what its effect would have been upon the former life of the Maya. For this reason the agronomic survey was inaugurated. The field work of 1935 was done by Professor R. A. Emerson of Cornell University, and J. H. Kempton of the U. S. Department of Agriculture. Most valuable assistance was rendered, by Dr. Morris Steggerda, who made available the data and experience obtained in his thorough studies of the villagers of Pisté. The method followed in the investigation was that of interrogating the Indians in their milpas where their answers could be weighted by the observer's judgment. The area visited was limited largely to the State of Yucatán, though a brief trip was made to the region centering on the city of Campeche. The milpas studied were cultivated by the villagers of Pisté, Xochenpich, Oxkutzcab, Eklum, Aquil, Teabo, Tecax, Peto, Sabaquil, Campeche and Uayamon.

With the exception of the fertile belt extending from Ticul to Peto, on both sides of the hills, estimated yields are remarkably uniform, falling, within the range of 1–1.5 cargas per mecate (33 bushels per acre [4046.9 square m]), for the first crop following the burning of the bush, and approximately one-half to three-quarters of the first year yields in the second season, after which time the land is abandoned to bush. In the poorer regions east of Chichén Itzá these estimates are halved for both years, and in the fertile country they are doubled or even tripled.

Although these are merely estimates, they are far from unsupported guesses. Dr. Steggerda's studies show a remarkably uniform consumption of 1.6 pounds of corn per adult per day. For the standard family of two adults and three minor children the annual consumption of corn, therefore, is about 45 bushels. To produce this amount of corn with a yield of one carga

per mecate requires between 3 and 4 acres [0.012–0.016 sq km], which is the amount of land most of the Indians claimed to farm. Estimates of acreage can be made more accurately than, estimates of yields, and the actual size of the milpas could not have differed greatly from the given size without detection. Further corroboration of the estimated yields is found in the estimated acreage in the fertile hill region where the number of mecates in a family milpa is about half that in the vicinity of Chichén Itzá.

There is no question about the decline in yield of the crop grown the second year following the burning of the bush. Some ascribe the drop in production to loss of soil fertility, others think the difference is due to the small quantity of ashes from second year burns and still others blame the weeds. From field observations the latter explanation seems the most important, though undoubtedly all three are operative. With one or two minor exceptions there was no difficulty in determining from mere inspection of the weeds and returning bush whether a given milpa was in its first or second year.

In the second-year milpas, the general practice is to cut weeds twice or even three times, and when it is understood that it takes more time to weed a mecate of land than it does to fell the bush one wonders why a second crop is ever attempted. Possibly in the days of stone axes, cutting new bush was more of a task than now and the practice of growing two crops has persisted from ancient times.

In the fertile lands milpas are weeded every month during the growing season. The necessity for this frequent weeding limits the grower to an acreage not more than one-half to one-third that planted elsewhere in Yucatán, but the Indians believe that the high yields compensate them for the smaller acreage. Actually, in corn, production per man the fertile region enjoys no advantage over the Chichén Itzá area. If anything, the man hours required per unit of corn are slightly greater in the fertile regions.

Following the second crop, milpas are abandoned to return to bush. Estimates as to how many years are required before the second growth of bush is large enough to burn are very unsatisfactory and those estimates can not readily be checked. The estimates range from 8 to 18 years with most replies centering around 8 to 10 years. The actual time required for the bush to regain burning size should be determined, as this period constitutes the greatest unknown factor in calculating the population a given region is capable of supporting.

At none of the places visited either in Yucatán or Campeche does grass seem to be a factor in corn production nor in the re-establishment of the bush. A few acres of grass were found, but these had been planted for pasturage.

No milpas were seen that indicated savannas would replace the bush after corn cultivation had been abandoned. Neither does it seem likely that soil erosion is of any importance in the agriculture of Yucatán or Campeche.

No evidence of destructive bush fires that might result in deforestation and subsequent denudation of large areas was found. So far as the observations of this survey go, the bush seems to re-enter abandoned land rapidly whether such land be small clearings surrounded by mature and seeding bush or whether it be large sisal plantations kept cleared for several years. The recovery of the bush, therefore, would seem to be assured under the agricultural practices followed at the present time. Whether or not this conclusion would hold under more extensive occupation of the land is a matter for investigation.

If the bush can be cut every 8 or 10 years following two years in corn and the land produce grain at the rates indicated, there seems to be no reason why this type of agriculture can not continue indefinitely. Even though the time required for the bush to attain cutting size is increased to 20 years, the land seems capable of supporting a population (at its present level of subsistence) of approximately 50 persons per square mile [2.6 sq km] employed in agriculture and an additional 10 persons who may reside in urban communities and engage in non-agricultural activities.

The State of Yucatán produces the maize support for the city population of Mérida and Progreso and for much of the labor used on the henequen plantations. It is evident, therefore, that in normal years the present agricultural population, using the methods of culture presumably practiced by their temple-building forebearers and improved merely by the substitution of simple metal tools for those of stone, is capable of supporting a large non-agricultural society. Yet the most striking thing about the Yucatán bush is the sparseness of the population and the low percentage of potentially productive land actually utilized for growing food. Given a strong administrative control, the present agricultural population could be forced to double its grain output, thus making possible the food requirements of a non-productive population 4 or 5 times that of the present urban one.

Present practice gives a marketable surplus over the requirements of the producer of approximately 20 percent of the crop. If the production per man were doubled by increasing the area cultivated and by intensive destruction of weeds, at least 4 times as much corn would be available for market as is now the case. If the grain output is doubled by doubling the agricultural population, then the non-producing population could only be doubled also since the ratio of grain consumed to that marketed would remain the same.

Probably in ancient times the production per man was greater and the agricultural population was larger than at present. Thus it seems safe to conclude that in the past the agricultural population was large enough to insure the food requirements of a non-agricultural group (priest, warrior, artisan or noble), larger than the present urban population of the state.

No evidence has been discovered of any form of intensive agriculture, other than the modern fruit tree cultures in the hill region. Indeed, the topography and rock outcrop is such that intensive agriculture in any form now known out of the question.

In a general way the agriculture of the present differs from that of the past in two particulars. The introduction of domestic farm animals has forced the Indian to fence his crop as a protection against the depredation of these beasts. Although the fences are not examples of geometrical precision, they do represent much labor and the withdrawal of an appreciable amount of small bush from the burn. The investment of labor in these fences may well be a contributing factor in the use of milpas for a second year, despite the fact that it would require less total hours of labor to burn new bush each year. On the other hand the animals encourage farming at greater distances from the villages in two ways. First they provide easy transportation of the harvest to the village home and second, since most of the animals are kept around the village, the remote milpas often need not be fenced. In the agricultural economy the introduction of the beasts of burden probably represents a loss of efficiency since they could not be used (because of the nature of the terrain) in the actual production of crops, but merely in transportation. It is doubtful whether in view of their food requirements they transport enough more than a man carries to represent a real saving of food. They must, therefore, be considered merely as a social improvement and an agricultural retrogression. Without them the farmer would bear more burdens, but would save labor in corn production.

The second difference of present-day agriculture over that of the past is the disappearance of cotton, and to some extent tobacco as cultivated crops. Cotton culture has been completely abandoned and tobacco is a rarity. Probably the latter crop was never as extensively grown as cotton. Cotton, on the other hand, is a necessary now purchased with maize.

Just how much land and time was devoted to cotton by the ancient Maya can not now be determined. If this product did not enter extensively into interregional trade but was used solely to clothe the resident population, probably less than 5 percent of the land in crops was utilized in growing cotton. On the other hand, if owing to its ready portability and high value as a finished product it served, as an article of barter, much

more land could have been given over to its cultivation. Land and time so used would have to be subtracted from that allotted to the production of food for the non-agricultural population.

So far as this preliminary survey can be considered trustworthy, the following conclusions are suggested: 1. The milpa system is the only one practicable in Yucatán even with modern tools and farm animals and there is no evidence that the milpa system as followed with two years in maize to 8 or 10 in bush could not continue indefinitely; 2. So far as the limits imposed by the bush alone are concerned this region can support 50 persons per square mile [2.6 sq km], together with 10 non-agricultural inhabitants concentrated in cities; 3. Maize culture has entirely supplanted that of cotton, though beans and squash are usually interplanted with maize and a small amount of tobacco is, planted in certain regions; 4. The crops no longer grown are purchased with maize, so that the cultivated area required by each family has not been greatly altered; and, 5. These conclusions are subject to large errors, since there is no definite record of the rapidity with which the bush regains burning size, nor have we any certain information on the yields obtained when the bush is cut the second time. It is possible, therefore, that the number of years which must elapse following a corn crop before the bush can be burned again is much greater than 10 or 12. In evaluating these conclusions it should be kept in mind that they represent the digest of information collected on a trip of only one month's duration. They are, therefore, something in the nature of opinions that must await careful investigation for their ultimate verification or disproof.

3.5.

J. H. KEMPTON AND
WILSON POPENOE
Maize Investigations

YB 35:138-140, 1936

Civilizations, like armies, progress on their stomachs. Without an assured food supply neither can advance. Agricultural practices that release the greatest numbers from the production of food provide the best conditions for the development of the other arts and of the sciences by which the cultures called civilizations are

evaluated. Even under our highly organized and efficient social order, about one-quarter of the labor of the average wage earner is required to obtain the family's food. Viewed from this standpoint the agricultural American Indians are not our inferiors.

The development of the corn plant and the mastery of its culture made the American Indian civilizations possible, if indeed the expanding agricultural art did not make the civilizations. At the time of the Discovery the corn civilizations were highly developed and the archaeological evidence shows that maize was a cultivated cereal at least as early as the beginning of the Christian era.

The origin of this cereal, which is the most valuable crop produced in the United States, is an unsolved mystery. It is known that maize is a purely American plant unknown in the Old World until the voyage of Columbus. The creation of this cereal is an achievement of the American Indian, and an understanding of its origin would contribute to solution of the problem of the antiquity of man and of agriculture in America.

The closest relative of Indian corn is a broad-leaved grass, *Euchlœna*, usually known by its Aztec name, *teosinte*. There are two species of this grass, one an annual, the other a perennial. Both are found in Mexico, commonly around the margins of cornfields. Until recently *Euchlœna* was unknown in the wild state outside of Mexico, but in 1932 Dorothy and Wilson Popenoe found it in southern Guatemala.

Although the relationship of teosinte to maize is so close that the annual species produces fully fertile hybrids in crosses with maize, botanists are not in agreement as to what position teosinte occupies on the maize family tree. All are agreed, however, that it is associated with the origin of maize.

At the present time the distribution of teosinte demarks the presumptive region in which maize originated, since it is self-evident that all domesticated organisms, whether plants or animals, have been derived from wild ancestors. Accordingly, as part of the project concerning the origin of maize and the maize culture of the Indians, an expedition was put into the field in Guatemala in October 1935, with the object of determining the area occupied by teosinte in southern Guatemala and the connection, if any, between the teosinte of Guatemala and that of Mexico.

The personnel of this expedition consisted of Dr. Wilson Popenoe, of the United Fruit Company, and Mr. J. H. Kempton, of the U. S. Department of Agriculture.

The expedition first visited Jutiapa in the Department of the same name, where the Popenoes had discovered teosinte in 1932, and from there proceeded to El Progreso and to Lake Retana, the latter in the ad-

joining Department of Jalapa, finding teosinte in abundance in both places. The La Paz drainage basin including Lake Retana and Lake Atescatempa in Guatemala and Lake Guija in El Salvador, were visited, but teosinte was not found far south of Lake Retana and appeared not to grow below 3,000 feet [910 m]. Inquiry disclosed that it grows at Moyuta and at Papaturro, both in the Department of Jutiapa, so that in southern Guatemala this plant occurs sporadically within a triangular area having Lake Retana, Moyuta and Papaturro as the points. Within that region this grass is well known under its Aztec name, teosinte, which may have been assigned during the Aztec occupation of this territory in pre-colonial times.

From El Salvador the expedition retraced its steps to the Department of Huehuetenango in northwestern Guatemala to visit Camoja, from which locality Weatherwax had reported teosinte. This report proved to be unfounded, but as the expedition moved on toward Mexico a vast acreage of teosinte was discovered centering on the town of San Antonio Huista in the valley of the Grijalva River. There teosinte, known locally by the Jacaltecan name *silica* or *solicit*, is the dominant plant in the vegetation, completely occupying the steep slopes and tablelands between 4,000 and 5,000 feet.

Although the plants were just flowering on October 31 it was apparent that in the characteristics of the rachis segments this teosinte closely resembles the Mexican form. Cytological material was collected and a subsequent study of the chromosome morphology by Dr. A. E. Longley places this form in an intermediate position between the teosinte of southern Guatemala and that of Mexico.

The expedition next moved on to Jacaltenango and thence to Nentón. A few scattered plants of teosinte were found at both places, but Nentón proved to be the northernmost locality for teosinte in Guatemala. From Nentón a visit was made to the Finca Chanquejelve where Oliver La Farge had observed what he believed might be a primitive corn or a maize ancestor. What he had taken for a small ear of corn proved to be the spadix of an aroid (*Spathiphyllum friedrichsthali* Schott).

Shortly after leaving the Finca Chanquejelve the expedition entered Mexico where the region in the state of Chiapas between Gracias á Dios and Tuxtla Gutierrez was traversed via Comitán, San Cristóbal and Acalá, without discovering teosinte anywhere along the route. Since the Huista River is a tributary of the Grijalva it was expected that teosinte might grow along its course, but though the conditions, except altitude, seemed favorable for its occurrence it was not found.

As a result of the expedition it seems certain that teosinte at the present time is more abundant and less

restricted to cultivated areas in Guatemala than in Mexico. In so far, therefore, as this plant may be considered as directly involved in the creation of maize, the most probable region for the origin of maize would appear to be the highlands of western Guatemala.

3.6.

G. W. COLLINS, J. H. KEMPTON,
R. STADELMAN¹

Maize Investigations

YB 36:149–150, 1937

As part of the research on the origin of maize and the distribution of maize relatives, Messrs. Collins and Kempton made an expedition in October 1936, through the region of Mexico where the states of Chihuahua, Durango, and Sinaloa meet. This expedition was undertaken to establish definitely the identity of a maize-like grass discovered near the town of Nobogame, Chihuahua, in 1895 by Lumholtz.²

The expedition proceeded from Santa Barbara, Chihuahua, by pack train into Nobogame via Cerro Prieto and Guadalupe y Calvo. The return trip was made through Guanacevi and Tepehuanes to Durango City. Much of the route was at elevations in excess of 9,000 feet [2,740 m] and largely through heavily forested country sparsely inhabited by primitive Tarahumara Indians.

At Cerro Prieto and at Nobogame, both approximately 7,000 feet [2,130 m] in elevation, the expedition found the maize-like grass described by Lumholtz. It proved to be teosinte (*Euchloenana mexicana*), the nearest known relative of maize. There was no evidence that the plant was utilized in the manner reported by Lumholtz. The Indians make no attempt to eradicate it from cornfields. Neither do they use the plants for forage, despite the fact that mine pack trains cause such a demand for forage that most of the common cornfield weeds are husbanded for this purpose.

At Cerro Prieto the area occupied by teosinte did not exceed half an acre [2,023 square m] and the plants found there may be the descendants of the seed transported from Nobogame as reported by Lumholtz.

The distribution of teosinte around Nobogame is more extensive than at Cerro Prieto, the plants occurring along stream banks over several square miles. Although there is unmistakable evidence that at one

time the region around Nobogame was widely cultivated, this is no longer true. The Indian population has been reduced to a few families and the area occupied by maize is small.

At both Cerro Prieto and Nobogame maize fields were common and the flowering season of maize and teosinte coincided. As would be expected, natural hybrids between maize and teosinte were found in both localities. The persistence of teosinte at Cerro Prieto, where it is overwhelmingly surrounded by maize, affords a demonstration of how this plant can survive for generations and retain its identity. The question is raised as to how much of the distribution of this plant is the result of human effort.

The discovery of teosinte at Nobogame extends the range of this maize relative 200 miles [321.9 km] farther north than it had been known before and to that extent enlarges the possible area within which maize may have originated.

Morphologically the teosinte at Nobogame and Cerro Prieto is indistinguishable from that found not far from Durango City, where additional collections were made by the expedition. It is considered not improbable that teosinte may have been transported by man to Nobogame from the Durango region, possibly with maize.

An understanding of how ancient populations met their subsistence requirements is essential for the reconstruction and evaluation of their civilizations. Accordingly, with the object of learning as much as possible about the agriculture of the Indians now resident in the region of the Maya culture Mr. Stadelman has been stationed in the highlands of Guatemala since early January.

In choosing the site for this investigation consideration was given to the racial composition of the population, to its relative freedom from European influence, its independence of an industrial outlet, and, since aboriginal agriculture in the Americas was primarily corn-growing, to the importance of this crop in their present economy. These major considerations and a host of minor ones led to the selection of Todos Santos, an Indian village in the Department of Huehuetenango in northwestern Guatemala, as the base from which observations would be made.

The present season's corn crop, planted in January, will not be harvested until October and therefore only tentative conclusions from preliminary records are possible.

The study indicates that in the region of Todos Santos an Indian family of two adults and three children can obtain their subsistence requirements from the product of 4 acres [16,187 square m] with a labor expenditure of approximately 150 man-days. Evidence has been obtained that an effort is made to combat

erosion on the steep mountain-side farms, and the practice of fertilizing the soil with animal manure has been adopted by some Indians.

The initiation of this investigation at this time proved fortunate, as the adoption by the Guatemalan Government of the work-book system, whereby every able-bodied adult male must prove employment for 150 days each year, or work out the difference on the public highways, will tend to standardize the time spent on the farms at this figure.

NOTES

1. Participation in the Division's program of Messrs. Collins and Kempton, members of the staff of the Bureau of Plant Industry of the U. S. Department of Agriculture, has been made possible through the good offices of Secretary Wallace and of Mr. F. D. Richey, Chief of the Bureau of Plant Industry.

2. "Around Nobogame grows a plant called maizillo or maizmillo. It is more slender than the ordinary corn plant and the ears are very small. It grows among the corn and has to be weeded out, as it injures the good plants. However, several Mexicans assured me that when cultivated, the ears develop. After three years they grow considerably larger and may be used as food. A man in Cerro Prieto raises this kind only; others mix it with the ordinary corn. I was told that people from the hot country came to gather it, each taking away about one almud to mix with their seed corn. The combination is said to give splendid results in fertile soil. Can this possibly be the original wild plant from which ordinary Indian corn has been cultivated?" (Lumholtz 1902:429).

3.7.

C. L. LUNDELL

The 1938 Botanical Expedition to Yucatán and Quintana Roo

YB 37:143–147, 1938

In continuation of the biological survey of the Maya area, under the joint auspices of the University of Michigan and the Carnegie Institution of Washington, botanical investigations were undertaken in Yucatán and Quintana Roo, Mexico, from May 27 through August 3, 1938, by the writer, and Amelia A. Lundell, who served as field assistant. The expedition, supported by the Horace H. Rackham School of Graduate Studies, and the Faculty Research Fund, University of

Michigan, carried out intensive explorations in the coastal area 40 miles [64.4 km] east and west of Progreso, around Chichén Itzá for a radius of 20 miles [32.2 km], and in the vicinity of Cobá, Quintana Roo. Important but smaller collections were made along the road south to Uxmal and around Mérida. Facilities of the Carnegie Institution of Washington at Chichén Itzá, generously placed at the disposal of the expedition, contributed substantially to the success of the field work.

The State of Yucatán has been worked more extensively by resident collectors and visiting botanists than any other part of the Yucatán peninsula, yet few data have been gathered concerning such important subjects as the general aspects of the vegetation, zonation, abundance and distribution of species, successional stages, relic forest areas and their importance in the interpretation of the natural climatic climax forest. Biotic influences, which include the effect of milpa agriculture and fire destruction, have been largely ignored. Hence these subjects were given primary consideration. In the course of the studies, approximately 8,000 herbarium specimens were collected, included among which are adequate series of such difficult groups as cacti and palms. Many of the described endemics some known from single collections without locality data, were rediscovered and gathered repeatedly with both flowers and fruits. A few species, some characteristic of the Yucatán and Quintana Roo forests, appear to be new to science. Clear taxonomic interpretation of a number of species and some genera, heretofore inadequately known, will now be possible from the ample herbarium material obtained. To substantiate and amplify ethnobotanical data, this subject received special attention in the Chichén Itzá area with the able assistance of Mr. Francisco Campos, who served as our interrogator of Maya herb doctors and farmers. The extensive collections from Cobá, the first large series from the interior of Quintana Roo, reveal an astonishingly close floristic and physiognomic relationship between the East Coast forest and the older forest of Yucatán. Collections of reptiles and amphibians from Chichén Itzá and Cobá, and fish from Lake Cobá and Lake Macanxoc, Quintana Roo, were made incidentally to the botanical work.

It is premature to describe the vegetation of Yucatán and Quintana Roo before the collections have been identified and the extensive field notes critically analyzed, hence the following preliminary discussions should be considered tentative and subject to revision.

The dry coastal area, east and west of Progreso, consists of three distinct physiographic zones: 1. the sand dunes lying between the sea and the cienaga; 2. the shallow cienaga and salt flats; and 3. the limestone flats extending for about 10 miles [16.1 km] south from the edge of the cienaga into the interior.

The sand dunes, in areas remote from the coastal settlements, support low thickets ranging up to 15 feet [4.6 m] in height. Around Progreso and other villages, cutting for wood, charcoal, and other needs keeps the vegetation down so that it scarcely exceeds 5 feet [1.5 m] even in the most favorable spots. The abundant treelets and shrubs of the dunes include species in the following genera: *Metopium*, *Coccoloba*, *Thrinax*, *Coccothrinax*, *Hippocratea*, *Maytenus*, *Bumelia*, *Capparis*, *Lycium*, *Agave*, *Jacquinia*, *Rhacoma*, *Thevetia*, *Caesalpinia*, *Cordia*, *Tournefortia*, and *Gymnopodium*. Cacti are locally abundant, but nowhere as common as in the area south of the cienaga. Of particular interest is the occurrence on the sand dunes, as shrubs or gnarled treelets, of such species as *Achras zapota*, *Krugiodendron ferreum*, *Thevetia peruviana*, and *Metopium brownei*, all of which are large trees in the wet forest to the south.

The cienaga, a shallow salt-water swamp behind the dunes, has wide areas of open water with islands of mangrove. The bordering flats usually are covered with mangrove, or in open areas with *Salicornia*, *Batis*, and other halophytic herbs.

From the southern edge of the cienaga low limestone flats, interspersed with rainy-season ponds, have a distinctive vegetation which extends inland for approximately 10 miles [16.1 km] in the Progreso region. Because of the high percentage of endemics and the predominance of cacti, this xerophytic belt, where rainfall does not exceed 20 inches [50.1 cm], is one of the most interesting phytogeographical areas in the peninsula. The vegetation reaches a height of 45 feet [13.7 m] in undisturbed sections, but averages much less in the proximity of villages owing to culling and clearing. The large cacti, *Nopalea gaumeri*, *N. inaperta*, *Pachycereus gaumeri*, *Lemaireocereus griseus*, and *Cephalocereus gaumeri*, are abundant, forming almost impenetrable thickets in undisturbed sections. Low cacti, *Opuntia dillenii*, *Acanthocereus pentagonus*, and several other species, not identified, are locally conspicuous. The interesting low species of *Neomammillaria* abound here only. Species in the following genera are the principal associates of the cacti: *Acacia*, *Mimosa*, *Pedilanthus*, *Agave*, *Haematoxylum*, *Euphorbia*, *Prosopis*, *Zanthoxylum*, *Pithecolobium*, and *Croton*.

Inland from the cactus thicket zone, the limestone plain rises slightly, extending unbroken southward to the low sierras bordering Yucatán on the south and southwest. With increase of rainfall from the coast inland, the vegetation undergoes a marked transition, although this transition is masked by invasion of species from the dry-cactus zone, a result of biotic disturbances. The greater part of the State of Yucatán, not planted in henequen or cleared for milpas, is covered with low thickets from 10 to 25 feet [3.1–7.6 m] in height. These are all second growth, the result of repeated

clearing and fire destruction. Two species of legumes, *Acacia gaumeri* and *Mimosa hemiendyta*, both native to the peninsula, are the principal dominants, with a host of shrubs and vines as associates. This widespread assemblage, often considered to be the typical vegetation of Yucatán, is nothing more than an early successional stage.

In a country which has supported as large an Indian population as Yucatán, thinly settled outlying districts are likely to contain the only sections of forest little disturbed, by man. In the search for data with which to reconstruct the appearance of the old climax vegetation of Yucatán, borderline country, far from villages and outside the limits usually reached by milperos, was combed. Here stands of advanced forest, with relics of *Achras zapota* and other slow-growing hardwoods, were discovered.

The floristic composition and physiognomy of the advanced and relic forest stand out in marked contrast against the widespread young legume thickets. The height usually exceeds 50 feet [15.2 m]. Species rare in the young thickets are here abundant, whereas *Acacia gaumeri*, *Mimosa hemiendyta*, and other associates of the low rank growth are comparatively rare. Principal trees of the advanced and relic hardwood forest include the following: *Lysiloma bahamense*, *Vitex gaumeri*, *Metopium brownei*, *Piscidia* spp., *Swartzia* spp., *Lonchocarpus* spp., *Achras zapota*, *Coccoloba* spp., *Bursera simaruba*, *Caesalpinia* spp., *Thouinia paucidentata*, *Torrubia* spp., *Hippocratea* spp., *Albizia* spp., *Guettarda combsii*, *Byrsonima bucidaefolia*, and *Malmea* spp. Of the tall shrubs, the following are abundant: *Gymnopodium* spp., *Neomillspaughia* spp., *Diospyros* spp., *Eugenia* spp., *Acalypha* spp., *Croton* spp., *Hampea trilobata*, *Randia* spp., *Erythroxylon* spp., and *Bauhinia* spp.

The most extensive remnants of the old forest were found in the vicinity of Yokdzonoot, between the villages of Pisté and Libre Unión, and along the road from Chichén Itzá to Kaua. Scattered stands of old second growth along the road from Mérida to Uxmal have much the same assemblage of species. The relic forest east of Cobá, Quintana Roo likewise resembles the advanced forest near Yokdzonoot and along the Kaua road; in fact, the stands at Cobá differ little floristically, and the dominants are the same. We may conclude that similar forest probably extended at one time as a wide belt across the northern tip of the peninsula, possibly as far south as Peto and Champotón. Its southern extension along the East Coast is not known.

Throughout this zone, endemics outnumber in individuals all other species, therefore comprise the bulk of the forest mass. In 1936 a similar condition was observed in advanced forest on the limestone plateau of southern British Honduras.

The older forest of Yucatán, deciduous with few exceptions during the dry season, may be designated as advanced deciduous forest to distinguish it from the advanced, predominantly evergreen quasi-rain forest of southern Campeche, southern Quintana Roo, northern Petén, and northern British Honduras.

This advanced forest of Yucatán and northern Quintana Roo differs considerably in dominance and to a certain degree floristically from the southern quasi-rain forest. Of significance is the absence in the north of such typical southern species as the escoba palm, *Cryosophila argentea*. The distribution of species in such genera as *Gymnopodium*, *Neomillspaughia*, *Diospyros*, *Cryosophila*, *Acacia*, *Mimosa*, *Orbignya*, and *Swietenia* must be studied to obtain satisfactory data by which these two phytogeographical areas may be more accurately delimited.

In spite of the fact that the relic forest east of Cobá differs considerably from advanced forest in the vicinity of Old Empire ruins in southern Campeche and northern Petén, the forest covering the ruins of Cobá compares very favorably with forest covering such sites as Calakmul, Topoxté, Naachtún, and Yaxhá. On the Cobá ruins, *Brosimum alicastrum* dominates, with the following associates much in evidence: *Achras zapota*, *Cedrela mexicana*, *Talisia olivaeformis*, *Sabal* spp., *Protium copal*, *Thevetia peruviana*, and *Chlorophora tinctoria*. All these are important in the economy of the Maya. Of interest is the prominence of *Chlorophora tinctoria* and *Thevetia peruviana*, both of which occur as trees up to 10–16 inches [25.4–40.6 cm] respectively in diameter. Neither one has been observed on Old Empire sites heretofore. An orange grove of undetermined age was discovered in a plaza growing in the shade of high ramon forest. Could this grove be a relic from Conquest times?

The role of fire in the destruction of tropical forest is nowhere more evident than in areas of Quintana Roo visited. Beyond the village of Dzitnup, along the trail to Cobá, we rode for four hours through utterly desolated country. For at least six years, possibly longer, annual dry-season fires have swept through. In some places a few scattered large relic trees, *Vitex gaumeri*, *Metopium brownei*, and *Piscidia* spp., all noted for their fire resistance, still stand, which indicates that high forest covered the area previously, a fact attested to by Indians in Dzitnup. In some sections, not a living plant remained from the former forest, only fallen trees and standing skeletons. Not only has the forest been killed, but the destruction of the humus and roots by fire has resulted in complete erosion of the thin mantle of soil into underground crevices to leave barren stretches of white pitted limestone.

Approaching the ruins of Cobá, a section has escaped the fires for possibly two years. Here the rank

second growth consists mainly of *cecropias*, *acalyphas*, and morning glory vines. East of Cobá, fire destruction has not been as severe; the forest there, as already pointed out, resembles remnants of old Yucatán forest. The area of fire-culled forest is said by chicleros to extend unbroken almost to Tancah on the East Coast.

Fire destruction has been repeatedly emphasized as one of the primary controlling factors to be considered in the interpretation of the vegetation of the Yucatán peninsula (Lundell 1937:92–94). Failure to recognize its extent and importance is due probably to confusion of rank second growth with old hardwood forest. The desolate area between the village of Dzitnup and Cobá is a convincing demonstration of the widespread destructiveness of tropical forest fires.

In the reconnaissance of the forest covering the Cobá ruins, a new sculptured monument was encountered, which may be designated as Stela 25. It is located approximately 1,200 feet [365.8 m] east of Structure XXV (Thompson, Pollock, and Charlott 1932: Plate 14) in a shrine at the edge of a low mound. The base, which leans badly, stands to a height of 6 feet 7 inches [2 m]; the upper part, broken into two large pieces and several fragments, measures 7 feet 10 inches [2.4 m] in length, giving the entire stela a height of 14 feet 5 inches [4.4 m]. Its width in the center is 4 feet 4.5 inches [1.3 m], which is narrowed to 4 feet [1.2 m] just below the rounded top. From the middle, where it measures 13.5 inches [34.3 cm] in thickness, the monument tapers to the edges and top to a thickness of only 8.5 inches [21.6 cm]. Only the face is sculptured. The glyph-blocks, surrounding a large figure suggestive of those on Macanxoc stelae, are badly eroded. An unsuccessful attempt was made to lift the leaning base, for the sculpture on its protected face does not appear, as badly weatherworn. It is possible that a date could be obtained from this section.

Probably less than half of the ruins of Cobá have been mapped. Group, B extends to the north and northeast almost to Group D (Nohoch Mul), and eastward past Sacbé 8. This area, through which extends the new emergency airfield, should yield additional monuments. Two well-preserved temples on tall substructures have been revealed by the clearing at the east end of the airfield near Sacbé 8. Photographs of the temples, Stela 25, and the airfield clearing have been deposited in the files of the Division of Historical Research, Carnegie Institution of Washington.

3.8.

RAYMOND STADELMAN

Maize Investigation

YB 37:161–162, 1938

In previous reports there has been made clear the outstanding economic importance of maize throughout Maya history. There has also been stressed the significance, for studies of the rise and diffusion of native New World culture, of determining the place of this cereal's origin. The latter problem has been under attack for several years by Mr. J. H. Kempton of the United States Bureau of Plant Industry in cooperation with Carnegie Institution. During the past year Mr. Kempton, using material gathered on former field expeditions, has been engaged in laboratory investigations of the genetics of teosinte, a plant suspected to have been involved in the ancestry of maize.

Mr. Kempton has also directed the study which Mr. Raymond Stadelman has been making of maize agronomy in the highlands of Guatemala.

Mr. Stadelman took up residence in January 1937 at the Indian village of Todos Santos in the department of Huehuetenango, Guatemala, as reported in the last *Year Book* [Chapter 1.26]. He has now observed and recorded in detail the agricultural practices of a typical Indian community throughout a full agricultural year. This has enabled him to prepare a list of definite questions regarding the agronomic and economic aspects of maize culture which he is at present using for an extended survey of other towns in the highlands. The intensive and extensive information being obtained by Mr. Stadelman will provide, for the first time, accurate data upon farming in the mountainous parts of Guatemala, which will be of great value for comparison with similar data already collected by Messrs. Kempton, Emerson, and Steggerda in the lowlands of northern Yucatán.

3.9.

KIRK BRYAN

Soils and Climatic Chronology in Guatemala

YB 44:168–170, 1945

Dr. Kirk Bryan, professor of geology at Harvard University, spent two weeks in Guatemala studying recent deposits in the neighborhood of Guatemala City and in the Motagua Valley. He also made a short trip to Lake Atitlán and Chichicastenango in order to acquaint himself with the more westerly highlands ash basins.

The city of Guatemala is built in a wide valley dissected by broad, deep gulches (barrancas) and bounded by hills and mountains. It lies in the divide between drainage to the Pacific and drainage to the Motagua River and thence to the Atlantic. The valley floor is composed of tuff that was deposited as successive showers of volcanic ash. The tuff filled the valley near the city to depths of 1,000 feet [305 m] or more. It was also deposited on the hills but was almost immediately washed off into the valleys. Eastward toward the Motagua each valley had a filling of ash successively finer in grain and shallower in depth. As the height of the fill decreases eastward, it appears that concurrently with the filling of the valleys, runoff took place across the body of ash, so that there was a stream grade on the top of the ash of about 4,000 feet [1,220 m] in 30 miles [48.3 km], or 13 feet to the mile. In the Motagua Valley there is a terrace of waterworn pumice fragments that rises about 200 feet above the present river grade. It seems to be the river-laid equivalent of the tuff fillings of the tributary valleys. One must suppose that enormous quantities of ash were carried by rainwash off the slopes of the hills into the valleys and thence to the Motagua. Here the river transported most of the load into the sea, but was itself overloaded to such an extent that it built up its grade and formed the tuff terrace.

The origin of the ash showers is presumed to be in one or more of the great volcanoes which fringe the southwestern border of the Guatemala highlands. The tuff has not, however, been traced to any definite source. Toward the end of eruption the rate of fall decreased and became spasmodic. The upper measures of the tuff sequence near Guatemala City are distinctive. A typical section consists of the following members:

Table 3.9.1. Highland Geological Sequence.

	Feet	Inches
Soil, dark brown to black	0	6–8
Subsoil, dark brown columnar or blocky; in low places, columnar black clay from	1–2	6–0
Disconformity, erosion of shallow valley		
Pumice tuff (upper sand or arena)	3	0
Massive decomposed buff-colored tuff (talpetate)	6	0
Pumice tuff (lower sand or arena)	4	0
Decomposed buff-colored tuff grading down into massive undecomposed tuff (talpetate fino)	0–2	6–0
White to gray tuff	many feet	

The talpetate fino is an old land surface in which the previously deposited tuff was decomposed and converted into a massive yellow clayey layer of variable thickness. Over this surface pumice tuff was deposited by fall from the air. The fragments of pumice range up to half an inch [1.3 cm] in diameter. The material is used as building sand, hence its local name arena. The next layer is a decomposed tuff, very massive and compact. It is obviously a subsoil representing a long period of decomposition under a climate wetter than that of the present time. This compact massive material is used in local building as quarried blocks and as a constituent of sun-dried brick. It is therefore well known and is called *talpetate*, a word presumably related to the Mexican *tepetate*. The overlying pumice is similar in all respects to the lower pumice tuff.

These formations slope gently upward and, in places, extend to the slopes leading to the adjacent mountains. In particular, the upper pumice tuff mantles steep mountain slopes of older rocks along the Guatemala-Lake Atitlán highway as far as Mixco. Near Guatemala City these three formations are eroded in broad shallow valleys, which drain into the deep barrancas. One of these valleys extends from northwest to southwest through the site of Kaminaljuyú. At its lowest points it reaches the talpetate fino. The surface soil is dark brown to black, blocky silty clay, or clay. Intensive cultivation by prehistoric and modern people has disturbed the soil nearly everywhere. Also there are numerous borrow pits from which the prehistoric people obtained material for pyramids and other structures. Many of these pits were back-filled with debris, and the area has since been cultivated. It is thus difficult to find truly natural conditions. Obviously, however, the soil was developed only in part by weathering of underlying material. It is usually an unconformable blanket over the underlying formations and has been largely built up by the gradual fall of ash from nearby volcanoes. The soil processes operating on this continually increasing layer have produced the deep

humus-bearing subsoil. In the lower areas, where water has stood in the rainy season, the subsoil is a columnar black clay. On better drained sites it is a blocky silty clay and in places shows fragments of the underlying pumice tuff or talpetate.

It appears that the existing climate, with its strong dry season, produces a soil that accumulates calcium carbonate in the sub soil. It is therefore a climate on the arid side. There is a break in the sedimentation between the soil and subsoil and the upper pumice tuff represented by the erosion of the broad valley already referred to. One must suppose that the talpetate, which is an old subsoil of the ferric oxide-aluminous type, was formed in a climate wetter than that of the present. This epoch, however, was far anterior to the earliest known culture of the area. As shown by the excavations of the Carnegie Institution, the oldest pottery of the site, when found in undisturbed areas, occurs at the base of the soil just above the jointed clay. In many localities the soil, subsoil, and part of the underlying material arena or talpetate has been excavated. The back-fill may be three feet or more thick and may contain pottery of any age. The soil and subsoil appear to represent a continuous period of growth by accretion of wind-borne volcanic dust and of soil formation under a pine-grass cover. The soil phenomena of the remote past, as represented by the talpetate and talpetate fino, record wetter conditions. Within the period of known prehistoric occupation no detectable change in climate is indicated by the soils.

JOSEPH A. HESTER, JR.

*Agriculture, Economy and Population
Densities of the Ancient Maya*

YB 51:266-271, 1952

Under an Institution Fellowship a study is being made of geographical conditions which could have affected the economy of the Maya civilization, particularly in the State of Yucatán. The intent of this project is to investigate the agricultural possibilities in Yucatán, within a framework of aboriginal technology, with the hope of arriving at a somewhat firmer basis for an evaluation of Maya economy, and perhaps a more realistic estimate of aboriginal population densities.

The artifacts which give substance to archaeology include more than the durable remains of architecture and implements. It is almost inevitable that a culture which has occupied an area as large as the peninsula of Yucatán, and occupied it intensively over a period of many centuries, should have left its mark plainly upon the region. Though increasing social elaboration, as evidenced in the architecture, mythology, and Spanish chronicles, certainly required the presence of the Maya in urban centers, it also required that they go farther afield in the satisfaction of their consequently heightened economic needs, and that they intensify the technology already at hand. In Yucatán, as elsewhere in the Americas, since there existed little significant mechanical means and no motive force other than man himself, the residue of aboriginal, economic life in all probability is confined largely to various aspects of agriculture.

It is abundantly apparent from the literature on Maya archaeology that authorities are by no means in accord in their estimates of population densities during, for example, a period of intensive occupation of the peninsula in pre-Columbian times. It has been held by some authors that the voluminous and often intricate architecture demanded large populations with high density. Others have pointed out that the agricultural potential of the 100,000 or so square miles [250,000 sq km] of the lowland Maya area is much too low, on the basis of milpa agriculture, to support the large populations postulated on the basis architectural remains.

All estimates of population density which are projected into the past must depend on the common economic denominator, agriculture. With respect to this factor, it has been held variously by modern investigators that the surviving, and presumably ancient, milpa method of growing maize, the chief staple apparently throughout the time of the Maya habitation of the peninsula, is the most advantageous usage of the rather poor soil, and a ruinous method of cultivation which hastens the destruction of the soil.

Modern Maya agriculture requires relatively few tools and simple techniques, but considerable know-how. The milpa system apparently is wasteful of the natural vegetation, the soil, and presumably the fertility of the soil. Furthermore, it is the practice in Yucatán to plant a field for usually no more than two years and then to move to a new field from which has been cleared 10 or more years' growth of natural vegetation. The yield of maize declines in the second year of planting in a given milpa, a phenomenon apparently universal in the lowland areas. This has been attributed to such causes as decline in soil fertility; increase in competition from natural vegetation or "weeds," particularly grasses; inability to kill off insect pests when the field is fired during the second

season, because of insufficient fuel furnished by the light growth of the previous year; and loss of soil due to erosion of the exposed milpa during the first year.

Several contradictory observations regarding the apparent decline in soil fertility are under investigation. One is that in the northern and western parts of the State of Yucatán, where soil generally is thin, seemingly poor, and very rocky, henequen plantations are maintained year after year, sometimes in increasing production, and are replanted almost as soon as the old plants cease to be productive. Occasionally, in the three years or so before newly planted henequen shoots come into production, maize is seen growing between the rows of henequen. In other instances henequen plantations are adjacent to productive milpas. It seems to be obvious that henequen and maize do equally well on the same type of soil, and that henequen is not subject to decreased productivity due to prolonged use of the soil. A second contradiction may be that the natural vegetation does not seem to be noticeably affected by diminished fertility. By the second rainy season after a milpa has been abandoned to return to "bush," the soil is supporting a heavier growth of natural vegetation than it ever supported of maize.

It is hoped that the information gained by studying the agriculture and agricultural lands of the present-day Maya, added to the considerable data already published, will provide the basis for a study of Maya economy in aboriginal times. There are several ways in which this study is being approached. The first and most obvious is the ethnobotanical one. This phase is being pursued at Telchaquillo with the assistance of Daniel Vargas, a milpero with an intimate and extensive knowledge of food and medicinal plants in that area.

In pre-Columbian times the New World was rich in quality and quantity of domesticated plants. Mexico was one of the more favored regions in this respect. Modern Mexico is vastly more wealthy in diversity of agricultural products, largely because of the importation and adaptation of Old World plants. A basic assumption is being made in this study that, in general, no Old World plant has replaced a New World plant of the same type (e.g., starch plants) in any given locality unless the Old World plant offered some decided advantage. That is, the Old World plants for the most part now occur in Mexico as additions to and not as replacements for the pre-existing New World plants. Another, and perhaps self-evident, postulate is that the native American plants, particularly those which are important staple crops, were, for the most part, long adapted to the area in which they occurred at the time of Old World contact. Consequently, with proper discretion, certain plants, such as those of dietary staple rank, may be regarded as archaeological indi-

ces, less subject, in some ways, to outside influence than are monumental architecture and ceramics. Domesticated plants have a further advantage over inanimate objects in that they may be subjected to genetical analysis.

The ethnobotanical collection that is being made is expected to furnish further insight, once identifications have been completed and the Old World plants subtracted from the New, not only into aboriginal economics, but perhaps into the problems of prehistoric population movements as well, provided in the latter instance that the centers of domestication of the various plants are reasonably well established.

A second approach to the agricultural problem comes through a limited study of the properties of the various soils of the peninsula. The area covered is largely the land bordering the paved and otherwise passable roads to which access may be had from Mérida. Soil specimens are being gathered every 10 km along the highways, wherever possible, and at archaeological and modern sites, in any event, at places which can be located readily on an accurate map. The purpose is to discover any soil types beyond the tolerance of maize. Conclusive tests have not been accomplished at this writing, but preliminary values, obtained in pH tests of the specimens already collected, indicate that few, if any, of the soils are too acid or too alkaline for maize cultivation. A probable exception appears to be the coastal sands within a few meters of the ocean. Ultimately it is expected that the soil samples will be subjected to a more thorough analysis.

A third approach is being made through a study of available water. This aspect goes farther than agriculture alone, for water is even more intimately associated with man's existence than is agriculture. The rains which support milpa agriculture were the limiting factor, ultimately, in the size of any aboriginal population on the peninsula, since they were the absolute limit upon the food supply. But availability of water during the dry season may have been the limiting factor in the ability of the Maya to realize the full production of their agricultural technology; thus, domestic drinking water is an important factor in the ecological relations between the Maya and their habitat.

It was hoped that during the course of this study some relic of intensive agriculture would be found which would indicate that the larger cities of the Maya were not exclusively dependent on milpa agriculture. Some of the highest pre-Columbian cultures in the New World featured some form of intensive agriculture; for example, the elaborate and highly efficient terraced gardens of the Peruvian Andes, and the chinampas, or so-called floating gardens, of the Valley of Mexico, both of which continue in use in those areas today. The Peruvian terraces, particularly, are unmistakably

artificial, and clearly bespeak the agricultural, as well as the economic, intensity of the cultures which built them. They are often the product of considerable engineering and architectural skill, and have left a lasting impression on the landscape, something which the archaeologist can "sink his teeth into."

At the end of four months in the field intensive agriculture, particularly of the post-rainy-season variety, remains to be found in Yucatán, in the archaeological sense. It exists in the dooryards around present-day Maya huts, supported usually by water from wells, most of which were not in existence in aboriginal times. Terracing occurs on a minor scale. Occasionally a few cubic meters of soil are walled up crudely on the side of a cenote to allow a papaya tree to take root. What appeared to be agricultural terraces were observed at several places, but investigation indicated that these, in each case, were architectural remains which coincided by chance with a present-day milpa, and thus far none has appeared to have had a clearly agricultural origin.

Water supply is an important item in intensive agriculture. The Andean terraces in many cases derive their water ultimately from glaciers and snow fields; the chinampas are lacustrine phenomena. If evidence of intensive agriculture exists in Yucatán, it is to be sought near perennial sources of water. With this in mind, many cenotes and aguadas have been visited. None has proved of sufficient size to have contributed significantly to the economy of more than one or two families at most. The lakes of Cobá, the laguna of Chichancanab, and others in Quintana Roo and southern Campeche have not been visited. They are at least potential sources of information with respect to the question of chinampa agriculture or related techniques.

Two weeks were spent at Telchaquillo in March, and a similar period in May, in an examination of present-day agricultural methods and the question of water supply. Milpas were visited both within and outside the wall of Mayapán. Parenthetically, it should be noted that the soil in and around Mayapán appears thin, rocky, and of little value agriculturally to the local milperos, who frequently rent land for milpa in the town lands of Tecoh and Xcanchakan. A trip was made to eight so-called aguadas some, 15 km south of Telchaquillo and to several others about 8 km to the northeast. The "aguadas" appeared to be large, shallow cenotes rather than true aguadas. The essential difference between aguada and cenote seems to be that the water in the aguada does not communicate readily with the local water table, whereas the surface of the water in a cenote is, in fact, the water table. It was decided on the basis of preliminary inspection that two or more of the eight "aguadas" to the south could

have been significant in dry-season agriculture of an intensive character, but that their influence on the dietary of even the local peoples could never have been of any considerable importance. A quadrangle of ruins in total disrepair was located adjacent to Xtantani, the largest of the "aguadas" immediately south of Telchaquillo.

Visits were made to Kabah, Uxmal, and Chichén Itzá for a preliminary survey of what the agricultural problems may have been in those areas. It seems probable that agricultural conditions in the three regions differ to an appreciable extent in terms of soil characteristics, and that although the same techniques of cultivation may have been applied to all these areas in archaeological times, local conditions may have affected yields or even types of plants cultivated.

An attempt was made at each site to observe what the settlement pattern may have been, and to determine whether or not domestic dwellings were located within, or immediately adjacent to, the ceremonial centers, as presumably was the case at Mayapán. Within a 1.5 km radius of Kabah remains of small structures, which conceivably could be construed as house mounds, were noted, but at Kabah as well as at Chichén Itzá the vegetation was too heavy for adequate observation. About Uxmal there are extensive cleared fields, frequently, perhaps predominantly, with deep soil that, with care, probably could support a very heavy crop of maize over a long period of time. Observation here was much simplified, and it was noted that the lowest-lying lands usually contained deep soil in which no artifact other than an occasional, and perhaps recently deposited, sherd occurs. All architecture seemed to be confined to higher ground. The frequent hillocks usually supported some vestiges of building, but in each instance the architecture was judged to have been more elaborate than that of the majority of the presumed house mounds at Mayapán. The hillocks often contained near their summit some indication of a chultun, in or about which usually was noticed a quantity of weathered ceramic fragments. No remains whatsoever were detected of a "working class" domicile. It may be noted here that the renowned aguada, usually to be found a kilometer or so south and west of the dried up following the main ruin group, rainy season of 1951 and remained dry through at least the month of May 1952. The three preceding years are reported as having been years of subnormal rainfall.

Kempton, Emerson, Steggerda, and Stadelman, among others, have investigated and published on many of the problems of milpa agriculture. In the present study, it is hoped to extend their investigations into the problems of clearing the milpa with the known aboriginal tools, that is, without the use of

metal, and of the amount of work required to keep the field clear, particularly during the height of the rainy season, as compared with that involved in present-day "machete" cultivation. In connection with this study of aboriginal milpa technique, and as an examination of soil fertility, soil exhaustion, and the absolute amount of soil required to permit a stalk of maize to grow to maturity, a series of tests is being conducted in which the volume of soil is precisely measured beforehand, the plant being exposed otherwise to conditions as close to those in the milpa as possible.

JOSEPH A. HESTER, JR.

*Agriculture, Economy, and Population
Densities of the Maya*

YB 52:288–292, 1953

The study reported here continues as an investigation of the geographical conditions of the Yucatán peninsula which would have affected the economy of the Maya in ancient times [Chapter 3.10]. It includes the ethnological aspects of modern Maya agriculture and general economy which may be considered as having survived more or less intact, from pre-Hispanic times.

An experiment was conducted in clearing 10 mecates, slightly more than one acre [4,046 square m] of Yucatán forest without the aid of metal implements. The purpose was to determine what difficulties Maya, agriculturists once had to overcome in preparing fields for planting. Two plots were selected, one of four mecates within the village of Telchaquillo, and another of six mecates in the Telchaquillo public lands, 1 km south of the Mayapán wall. The latter site was purposely located in what was considered the highest native vegetation in the region, although the highest trees did not exceed 40 feet [12.2 m], and only half a dozen were higher than 25 feet [7.6 m].

No attempt was made to identify the various plant species here; they were representative of the typical Yucatecan bush (Steggerda 1941:100–107), characterized by great variety in which no single type dominated. Density of woody plants per mecate ranged from more than 100 to slightly less than 200; size of trees apparently was not a factor in the density per mecate of woody plants. Of the trees, from 30 to 50 in each mecate were 4 inches [10.2 cm] or more in diameter. In

the six mecate plot there were several habin (*Piscidia erythrina* L.) over 15 inches [38.1 cm] in diameter. These are reported to grow to heights of 80 feet [24.4 m] and are said by the workmen to have the hardest wood in the forest; the half-inch [1.3 cm] thick bark is still used occasionally for sandals and buckets.

The workers used no metal tools; leather gloves were supplied for part of the work. The experiment was carried out during the rainy season, in July and part of August. Vegetation at this time of year tends to be moist and crisp, and generally can be broken easily, although during the preceding dry season the same vegetation may have been dry and hard. For most of the vegetation, it was found possible for a man to break a trunk or branch up to 2.5 inches [6.4 cm] in diameter without assistance. For green vegetation heavier than this, the workers experimented with unhafted pieces of limestone, used as mauls or choppers. Sometimes a large block of limestone was used as a chopping block or anvil in conjunction with the chopper. After experimenting for two weeks with various sizes, shapes, and weights of stone, we discovered that entirely unworked limestone fragments could be utilized satisfactorily; such fragments, in convenient shapes and sizes, were plentiful. The choppers usually averaged about 5 inches [12.7 cm] wide by 9 inches [22.9 cm] long in their greatest dimensions, and 1 inch [2.5 cm] or slightly more in thickness. Some of these "fist-axes" were used for two weeks or more without becoming damaged beyond usefulness. Such material abounds in Yucatán. It is put to use readily and satisfactorily, and when discarded it shows no signs of having been used, other than vegetable stains which soon weather off. This may be considered a partial explanation of why some types of stone tool are so rarely identified in Maya archaeology.

Branches, foliage, and small tree trunks, when chopped or torn down, were piled in mounds about 10 feet high in which there was adequate drainage. It was found that the brush had dried sufficiently to be burned within two weeks from the time it was cut, even at the height of the rainy season. During the rainy season in Yucatán precipitation occurs typically in scattered, intermittent showers, and frequently a given area may receive no rain for two or more days. After such a brief rainless period, vegetation piled in high mounds may be burned easily despite dampness of the ground and high atmospheric humidity.

Trees too large to break down and too hard to chop through with blunt limestone tools were girdled. The bark was peeled away in bands a foot or two [31–61 cm] in breadth, a process requiring from 5 to 10 minutes per tree. The cambium layers of many trees, however, were tough and spongy, and difficult to chop with stone tools. There was sufficient moisture in the air at

all times during the rainy season so that moss or fungi soon formed a protective sheath on the surface of the cambium matter, shielding it from aridity, and at the end of the experiment it seemed probable that many of the girdled trees would survive. Had the branches and foliage been piled at the base of these trees, however, and fired toward the end of the dry season, as is done by many primitive peoples in clearing jungle for cultivation, these trees almost certainly would have been killed; at least their growth would have been retarded to such a degree that the ground beneath them could be cultivated for a year or two before the trees recovered their foliage sufficiently to shade out plants around them.

It was concluded that the clearing of agricultural lands in Yucatán with bare hands, unworked stone tools, and fire at the proper time can be accomplished as effectively as with steel axes and machetes. Without such metal tools, it is estimated that approximately twice as much time would be required to clear the land as is needed at present with metal tools. Nowadays, almost as much time must be devoted to fencing the plot as is required to clear it of vegetation. Fences have been necessary since the conquest, to keep out livestock, animals of Spanish introduction which, the Maya did not previously have. Since fences almost certainly were not needed in ancient times, the total time required for the preparation of a given area of land for cultivation under aboriginal conditions may be considered closely comparable, to the time required at present. Such clearing would be most effective during October and November, after the rainy season, but while the vegetation is still green. At this, time there is greater probability that the larger trees would be killed by girdling, without the use of fire.

Almost all the nonarable land in the state of Yucatán is confined to regions bordering the coast which are too wet for agriculture, or where soil is too thin or lacking. The arable land, probably more than 90 percent of the state's area, all comes under cultivation sooner or later, with greater or less frequency. Native vegetation covering the arable part of the state is characteristically low forest of secondary growth, usually referred to technically as "bush." The volume of vegetation above ground is indicative of the agricultural potential of the soil, consequently that land on which the highest bush grows is considered most desirable for agricultural purposes. But no large tract of land is left uncultivated over a period sufficiently long for the largest trees to realize their full potential growth. Thus the height of bush in Yucatán is a sensitive index of profitable land utilization in relation to population density and with primitive agricultural practices. Those areas in the east and southeast parts of the state in which the bush is relatively high are less densely

occupied. In the central and western region of the state, which there is no high bush, there prevails a relatively delicate ecological balance between the population and its economic medium, extensive maize agriculture, which indicates clearly that the population now has approximately reached saturation with respect to its economy. Because of food importation now into Yucatán, facilitated by manufactured exports, chiefly of henequen, the modern population density of approximately 30 persons per square mile [2.6 sq km] of productive farm land probably equals or exceeds the aboriginal maximum.

The mecate was used as the unit of areal measure in the experiment primarily because it is one with which the workmen are familiar and because it is the accepted unit of measure among the Maya at present. The word, however, is an introduction into Yucatán from the highlands of Mexico, stemming from the Nahuatl *mecatli*, and probably conceptually related to the Maya *kaan*. The mecate is used as both an areal and a linear measure usually, but probably erroneously, considered to be 20 m by 20 m, or simply 20 m long. In the vicinity of Telchaquillo the mecate was consistently found to be longer than 20 m, suggesting a surviving aboriginal unit of measure more meaningful to the Indians than its modern metric approximation.

For the experiment, mecates were measured by six lengths of a pole locally called *uah la che*, which was cut according to measurements memorized in terms of each individual's body dimensions. Usually such poles measured two arm spans plus some additional compensation, such as a hand's width, or the thickness of two or three fingers. The poles seldom varied more than a half-inch [1.3 cm] in length, although cut by different individuals. A similar pole, *píi zi che* (approximately), is used near Sayil; a mecate rope or *kaan* is used near Pisté.

It was observed that cultivated fields, would seem superficially to be plantations of maize only, may actually contain more than 24 varieties of cultivated food plants, although frequently there is no more than one variety of maize planted in a given field. For example, the assortment on one 50 mecate farm (approximately 6 acres [0.024 sq km]) was found to include four varieties of Old World melons, 10 varieties of beans or pulses, both native and foreign, two squashes, one (nonedible) gourd, a large assortment of tuberous crops-including two kinds of yams, three of sweet potatoes, sweet manioc, and two additional kinds of tuberous plants, one variety of chile, papaya, one variety of maize, and grasses. In this same field flowers of various kinds were grown for seed, to be planted later in the farmer's dooryard garden. The assemblage of food plants cultivated on this one farm did not exhaust the diversity of

plants locally available, but represented the farmer's personal tastes and preferences. Other men in the area planted different varieties of the same species, according to their individual preferences, selecting, for example, from more than half a dozen local varieties of maize, and from four or more of chile, etc.

Although grass is usually considered detrimental with respect to Maya maize agriculture, it was learned that some grasses actually are sown from seed in the richest soil among stalks of maize. Some of these grasses attain a height of 4 to 6 feet [m], and are used for roofing thatch. In some areas, grass thatch is considered superior in many respects to palm thatch (Wauchope 1938:108, 116). This finding also has some bearing on a statement by Bequaert to the effect that many of the weed grasses in Yucatán were introduced there by man, along with agriculture (Shattuck 1933:510).

In soil samples collected for analysis, roots of grasses were found to be quantitatively more abundant in the soil of lands which had been cleared but not burned adequately. Generally, in the second successive year of cultivation there is insufficient fuel to produce an adequate conflagration, by local standards. In such fields it was found that grass roots were an estimated 10 to 50 times more abundant in soil over which there had been only a light burn than in soil in the same field over which there had been as intense a fire as in the first year.

The role of fire in the preparation of fields for maize cultivation has long been a problem. Burning of cut brush *in situ* helps to control grasses in shallow soil and to minimize the insect menace, and it leaves ashes containing readily soluble mineral salts. Such minerals normally are the chief source of fertilizer received by the soil. But these salts are dissolved and leached rapidly through the shallow Yucatán soil, through the interstices in the bedrock limestone, and into the ground water, beyond the reach of maize and farmer alike. Unfortunately also, the humus which could retard such leaching is usually consumed entirely in the burning. This destruction of humus is a serious consequence of burning, for long-range fertility of the soil here depends to a high degree on humus content. For soil fertility in the season subsequent to first-year burning, however, the less competition there is from weeds, the greater are the chances that the crop plants will receive an adequate supply of minerals. The burning of cut brush in preparation for planting is the only immediately practical technique available to the Maya, both for clearing the land and for fertilizing the soil; but over the years it has the deleterious effect of maintaining the soil at an extremely low level of fertility.

The northern coastal bar of the peninsula was traversed from Punta Lastre (Punta Nimún) in northwest-

ern Campeche to Boca de Dzilam, Yucatán, on the north-central Coast, to observe agricultural conditions and the source of the ancient salt supply. Agriculture on the coastal bars is precarious with respect to maize and other subsistence crops. Frequently the entire season's crop is lost because of insufficient precipitation; but for the years in which precipitation is ample, yields are reported almost double those for any other area in Yucatán. Most of the inhabitants of the coastal bar, outside the one major town, Progreso, work on coconut plantations and in fisheries or lumbering industries. Many Indians so employed cultivate small plots of maize on the mainland, about 4 to 6 km inland from the lagoon where soil and precipitation are adequate. It is assumed that this also was the practice in ancient times.

Salt continues to be gathered from the lagoon each year, toward the end of the dry season. Frequently only bare hands or a shell are used in collecting salt from the floor of the lagoon, a technique which cannot have changed significantly since the conquest. The salt is of comparatively high quality, is shipped for sale to other parts of Mexico, and locally is utilized for domestic and industrial purposes. One important use to which salt is applied is in Yucatán fisheries, in conjunction with commercial drying and preservation of fish.

Since aboriginal times, the only important change in the economy of those Maya living on the coastal bar is probably the addition of coconut plantations. Although the coconut almost certainly was growing in the New World before the Spanish arrived, the indications are that it was not cultivated in Yucatán until after the middle of the sixteenth century.

3.12.

JOSEPH A. HESTER, JR.

Maya Agriculture

YB 53:297-298, 1954

The 1953 field season, September through December, had a threefold purpose: to supplement a study of Maya agriculture begun in 1952, to compare Maya agriculture with surviving primitive agricultural practices on the Mexican mainland, and to make a cursory examination of archaeological ruins for possible aboriginal units of measure.

From the lowland Maya area in Chiapas, Campeche, Yucatán, Quintana Roo, and British Honduras were gathered data on approximately two dozen varieties of maize which can be considered native to the peninsula of Yucatán. These all, however, are tentatively identified as hybrid derivatives of no more than three of the group. The three basic races of Yucatán maize seem to be *nal tel*, small, yellow-grained, and precocious; *dzit bacal* (*olotillo* on the mainland), a slender-cobbed, 8-rowed white maize; and *xnuc nal* (*tuxpeño* in Veracruz), largest of Yucatán varieties, considered by some to be related to the "Southern Dents" of the United States. Through the courtesy of the Rockefeller Foundation, facilities were made available at the national agricultural college at Chapingo, Mexico, for a study of collections of Yucatán maize.

Certain basic differences between highland and lowland tropical primitive agriculture were noted. These could be attributed, not to apparent cultural differences, but to geographical differences, chiefly of temperature and precipitation. Abundant crude agricultural terracing was observed in highland valleys from the state of Hidalgo to southern Chiapas. Occasion-

ally rock-faced, the terraces for the most part are earth-faced or retained by rows of agave or other plants. Many terraces seem to have been abandoned for a long time, the abandonment often leading to disastrous and irreparable erosion.

In an effort to detect a consistent system of measure, measurements were taken of basic structural lengths and intervals, and of decorative elements, on ruined buildings at Tula, Teotihuacán, Monte Alban, Zempoala, El Tajín, Palenque, Uxmal, Chichén Itzá, and Xunantunich. A special, but inconclusive, effort was made to compare the Temple of Quetzalcoatl at Tula, Hidalgo, with its Yucatán counterpart, the Temple of the Warriors at Chichén Itzá. Although a near periodicity was found in the recurrence of certain lengths in the basic design of these two and other structures, no consistent unit of measurement was found to emerge clearly through the crude workmanship. More than a score of contemporary Maya terms for units of measure were recorded from informants in Telchaquillo, Yucatán, and in Soccotz, British Honduras, together with data on the manner in which these units are taken and the purposes for which each is used.

Problems in the Study of Maya Ceramics

YB 30:114–116, 1931

The general problem toward the solution of which the Division of Historical Research is directing its efforts was formulated and discussed by the Chairman in his report to the Trustees last year. The interpretation of the results of the “meeting of two races of diverse physical make-up and differing culture” must rest on a thorough knowledge of the constituent elements of the conflicting cultures. To that end the archaeologist is working; bending every effort to synthesize the data obtained, through a study of the various categories of material culture, in order that, finally, he may present an accurate picture of the state of Maya culture at the time of the introduction of European blood and civilization.

Of the various divisions of material culture which aid in the reconstruction of the history of an aboriginal people, one of the most useful is a study of their pottery. Frequently the only clue to the sequence of cultural periods has been furnished through a study of the potter’s product. Questions of origin, tribal movements, trade with contemporary peoples, the influence exerted through external contacts, and even minor os-

cillations of culture within a definite period any be solved in the story of the potsherd. The problem of the ceramicist is, then, to discover those factors in the origin and growth of Maya culture which are not readily ascertained through the study of any other medium.

The presentation of ceramic material in the literature has been little more than descriptive; no attention has been paid to the chronological. Arrangement of the wares, nor has the investigator tied his particular group into the whole range of Maya pottery. The most notable exception to this neglect of Maya pottery in the past has been the work of Dr. George Vaillant. In an unpublished manuscript, submitted in partial fulfillment of the requirements of the degree of Doctor of Philosophy at Harvard University, he has identified the major wares and arranged them in a partial sequence. This chronological sequence is based on evidence uncovered years ago at Holmul by Dr. R. C. Merwin and by Dr. Vaillant in the Group of the Phalli at Chichén Itzá. Careful consideration of the present status of ceramic investigation in the Maya area clearly

points to the need of accurately documented collections with which the great mass of existing material can be compared and consequently arranged in a time sequence. The specific problem is, then, the collection of stratigraphic evidence of the origin, growth and decay of Maya pottery.

Recent work at Chichén Itzá and at Uaxactún has demonstrated that this is not an impossible task and that it does not involve great projects nor the expenditure of large sums. Trenching in plazas, dead cenotes, low-lying areas near buildings will produce the evidence required. In those favorable locations where large sites are in the process of investigation, additional may come through the careful study of sherds from various parts of buildings, particularly those structures which have undergone architectural changes at different times in their history.

In dealing with the product of peoples high in the scale of cultural evolution, one is confronted with an enormous mass of material generally produced in a wholesale fashion. The nature of this product is such that it is capable of indicating only the great and abrupt changes in culture. In considering this mass it is necessary to find those wares, probably minor or special wares, or those modifications of the fundamental body shape, which are time carriers. The stratigraphic work at Chichén Itzá and Uaxactún has indicated that much valuable information will come from a careful study of rim form, changes in type and location of handles, and shifts in styles of decoration.

Further, a portion of this specific problem will be the study of the composition of the pastes of the different wares. An analysis of the clays and tempering materials used in the preparation of the paste and the location of the source of these substances should enable the investigator to identify the foreign wares from those made locally. Crude beginnings along this line have already demonstrated that certain wares could not possibly have been made in the region in which they are found, unless the clay used was imported.

With the exception of isolated descriptions of the present-day processes used in the manufacture of pottery vessels, little attention has been paid to this important field of investigation. It seems likely that a study of the various processes in use in the Maya area today may point to the solution of pre-Spanish problems which as yet can not be understood.

Finally, it is impossible to complete the story of the development of pottery making among the Maya without a wide knowledge of the ceramic product of contemporary neighbors of this people.

The best approach to a study of Maya pottery, in the opinion of writer, is one based on intensive research in regions which seem to have been centers of ceramic development. The territory of the Maya has been di-

vided into a series of geographic regions which seem to be, on the basis existing material, ceramic units as well. These districts, which are the same as those used by Dr. Vaillant in his unpublished manuscript on *Chronological Significance of Maya Ceramics*, are: 1. The Peninsula of Yucatán; 2. The Petén; 3. Copán-Salvador; 4. The Highlands of Guatemala; 5. The Ulúa Valley and Honduras; 6. Cobán and the Motagua; 7. Chamá and the Chixoy; and, 8. Chiapas and Southern Mexico.

It has seemed best to begin with the peninsula of Yucatán because of the great mass of documented sherd material which is now available from Chichén Itzá. The origin of the Maya ceramic group is one of the most important problems with which the archaeologist must deal. The recent work at Uaxactún and the earlier investigations at Holmul suggest that in the Petén study an indication of the source of Maya pottery may be forthcoming. The similarity of certain Uaxactún figurines to those of Salvador would indicate that a study of the Copán-Salvador material should follow. The next step is to consider the ceramic history of the highlands of Guatemala. Whether or not the other districts should be studied in the order named will depend on the results of the earlier work and, on the opportunity to carry out these investigations.

A ceramic research such as outlined above should eventually produce as complete a picture of ceramic development as it is possible to obtain. When all the material has been drawn together, and the full story of the origin, development and decay of the manufacture of pottery among the Maya is known, will it be possible to so correlate this data with the evidence from the other categories of material culture that we may describe with confidence any particular stage in their history? Shall we be able to demonstrate the value of a ceramic history to answer questions of culture growth and break-up when no other data are available? Can we safely interpret events in the life of a people with no other evidence than that furnished by important changes in ceramic styles and wares? Can we say that degeneration in pottery always precedes actual cultural decay? The ultimate problem from the ceramicist's point of view in these researches in Maya pottery may be stated as follows: "Is the complete story of the origin, development, and disintegration of the art of pottery making among any people an index of these same processes in their history?"

4.2.

H. B. ROBERTS

Ceramic Research

YB 32:86–88, 1933

The Section's study of the pottery of Yucatán was inaugurated in 1926 by G. C. Vaillant, who established a preliminary classification of the wares found at Chichén Itzá. The investigation, continued in 1930 and 1932 by Mr. H. B. Roberts, comprised thorough examination of the large sherd collections taken in previous years from excavations in various temples at Chichén Itzá; stratigraphic tests in several refuse deposits in the city; and organization with Mr. H. B. Pollock, of the Architectural and Ceramic Survey which, in 1932, resulted in accumulation of stratigraphic data from Cobá, Sabacché, Labná and Yaxuná. Review of the situation at the close of 1932 indicated that one more field season could be counted upon to complete the local ceramic picture and to furnish the evidence necessary for the relative dating of the more important buildings. It also appeared desirable to finish all contemplated work at Chichén Itzá before undertaking further activities in other localities, for it was evident that full ceramic data should as quickly as possible be made available for the use of those members of the staff who were engaged upon other archaeological problems of the site. Furthermore, it was felt that a well-rounded knowledge of Chichén pottery would permit new evidence accruing from extension of the Architectural-Ceramic Survey more readily to be fitted into its proper place in the general ceramic scheme. Mr. Roberts therefore decided to devote himself exclusively to Chichén Itzá in 1933.

During the field season (ending June 10) the sorting and classification of all ceramic material obtained, from the structures excavated by the Chichén Itzá Project were completed. The pottery found in 1932 and 1933 by Mr. Bolles in his study of the Monjas and associated structures was examined and classified. This material is archaeologically the best documented series from the city and covers the longest period in time of any collection studied. It will prove very valuable for making the final determination of the chronological sequence of Chichén Itzá wares.

The sherds taken by Mr. Ruppert from the Mercado-Southeast Colonnade group in 1932 were classified and studied in relation to those, from the large refuse deposit near that structure examined by Mr. Roberts during the same year. The pottery series obtained from these two locations correlate very well and provide an excellent ceramic picture of the period

during which the buildings were under construction and in use.

During the course of the season some 30 test pits, fairly well distributed over the city, were dug in areas likely to reveal stratified refuse. Sixteen of the pits were enlarged into trenches, located in the following groups: north of the terrace of the Group of the Initial Series, north of the terrace of the Principal Group of the Southwest, east of the terrace of the Group of the Hieroglyphic Jambs, east of the Group of the Sculptured Jambs, north of the House of the Deer and Red House, and Colorado, bajo north of the Temple of the Three Lintels, and bajo west of the Guest House. While the material from these trenches has not been sufficiently studied to allow definite and final statements, it seems certain that we now have a fair sample of the ceramic make-up of Chichén Itzá and that three main ceramic periods may be discerned: I. Pre-Mexican period, with pottery similar to that of the Labná-Puuc region; II. Period of Mexican occupation; and, III. A period following the era of Mexican domination, characterized by the return of certain earlier Chichén Maya forms.

The close relative dating of the sherds from individual buildings will be on the basis of sub-periods which have not as yet been clearly worked out.

It is believed that we are now in possession of data adequate for preparation of the ceramic history of Chichén Itzá which Mr. Roberts is at present engaged in writing. Further work would certainly add many details, but until new and improved methods for the study of pottery have been developed, such work does not seem justified.

In addition to the materials from Chichén Itzá, Mr. Roberts examined the sherds collected by Mr. Ruppert in southern Campeche. Although the collection is too small to warrant confident conclusions, it appears that the wares fall into groups which may roughly be correlated with certain architectural changes noted by the Campeche Expedition.

4.3.

H. B. ROBERTS

Ceramics

YB 34:126–127, 1935

The general program of ceramic research in the Maya area has been outlined in previous *Year Book* reports [Chapters 4.1 and 4.2]. In the continuance of this

investigation Mr. Roberts spent the period from the middle of November 1934 to June 1935 in the peninsula of Yucatán. The Ceramic Survey was, as in past field seasons, combined with the Architectural Survey under Mr. H.E.D. Pollock. This arrangement has proved mutually beneficial and at the present time is the most satisfactory method of conducting the Architectural and Ceramic Survey of the Maya area. Ceramic studies were carried on at Chichén Itzá, Sayil, Kabah and Holactún (Xcalumkin).

The ceramic material from Chichén Itzá examined and classified during the past field season consisted of the specimens collected by Mr. John Bolles in the spring of 1934. These potsherds were obtained in the excavation of the East Mound of the Monjas Group. This series completes the available ceramic data from the Monjas Group. The pottery from the East Mound is generally representative of the period of the Mexican (Nahua) occupation at Chichén Itzá and would seem to be typical of the phase nearing the close of that period. In some sections of this unit of the Monjas group, potsherds were obtained which represented wares characteristic of the post-Mexican (Nahua) stage in the history of Chichén Itzá, a period identified by the reappearance of pure Yucatecan-Maya forms.

Mr. Roberts also examined the ceramic material collected by Dr. S. G. Morley at Yaxacumché, a site near Oxkutzcab. The wares from this site are in the main similar to those from the Puuc region. About 10 percent of the rim forms wares are early in the chronological sequence of the pottery of the Puuc. The majority of ceramic specimens from this site are characteristic of the final phases of the historic development in the Puuc. There is an additional 10 percent of the wares from Yaxacumché which can not be identified by the writer at the present time. It is unfortunate that it was impossible to obtain a stratigraphic sequence of the above mentioned wares. The importance of ceramic material from this site can not be over-emphasized as it represents the first definite evidence of the spread of Puuc types beyond the range of hills known by that name in Yucatán. It is hoped that further work may be carried on in this region as it has, an important bearing on the general problem of the first Nahua invasion of the peninsula of Yucatán.

The ceramic survey of the archaeological area known as the Puuc was begun in 1932. Mr. Roberts was unable to continue this survey until the past field season when the sites of Sayil and Kabah were investigated. While the sherds obtained in 1935 have not been thoroughly studied and the data compared with those obtained in 1932, the preliminary sorting and classification of the material confirms the evidence obtained from Labná and the other sites investigated in 1932. The most important information obtained from

these two sites was the discovery in the lowest strata: of two trenches at Kabah of polychrome sherds of the same general type as those from Holmul V and Uaxactún III. Polychrome sherds of wares assignable to the above two periods have been found under stratigraphic conditions at two other sites in the Yucatán peninsula; namely, Cobá and Yaxuná. The Cobá and Yaxuná sherds were found in strata which did not contain any of the standard Yucatán-Maya wares. At Kabah the polychrome wares were found in direct association with the earliest of the Puuc wares and rim forms. It is interesting to note that these Petén wares occur at sites at which, with the exception of Cobá, no initial series dates have been discovered.

The chronological sequence of rim forms and wares in the Puuc area can now be arranged on the basis of actual stratigraphic evidence. The series begins with a type of pottery which has been identified as the polychrome of Holmul V and Uaxactún III and continues through the Yucatán-Maya wares to and including the introduction of Fine Orange, a ware which was Mexican in origin.

A factor of importance in the final determination of the position of the sites of the Puuc in the history of the Yucatán-Maya is the total absence of Plumbate. This ware has not been found in stratified deposits in any of the Puuc cities.

Since at Holactún (Xcalumkin) there occurs an initial series date, it was hoped that the ceramic material would throw some light on the general problem of the appearance of Petén polychrome wares in Yucatán. Mr. Roberts, however, failed to locate any refuse deposits which yielded this information. The data from this site are at present very perplexing. It has not possible to obtain any definite stratigraphy, but the majority of the rim forms and wares from the lower cuts were typical of the later phases of the Puuc. The mass of the material was similar to that of the Mexican period at Chichén Itzá. The Holactún pottery seems to represent a reoccupation of the site at a time post-dating the original construction of the city. Until the sherd series has been more thoroughly studied and further data collected, it is impossible to state the exact position of Holactún in the ceramic history of northern Yucatán.

In addition to the field investigations on the ceramic history of Yucatán, Miss Anna O. Shepard of the Laboratory of Anthropology of Santa Fe, New Mexico, has begun a technological study of the pottery of this area. The Mexican Government has kindly permitted the exportation of the material necessary for this research.

4.4.

ANNA O. SHEPARD

Ceramic Technology

YB 36:144–145, 1937

Of all archaeological materials, pottery is the most useful for tracing the development and spread of cultures, and for measuring the strength and identifying the source of external cultural influences. But its value for such purposes depends upon the certainty with which ceramic types can be recognized and defined, and upon the accuracy and uniformity of their description. Until very recently, however, pottery has been classified almost solely on the basis of its external characteristics, vessel form, color, decoration, features so subtly variable that their recording in terms sufficiently objective to be of service to other students is extremely difficult. Attempts have been made to use the more definite and tangible evidence offered by clays, tempering materials, and pigments; but success has hitherto been meager, because no archaeologist has had the highly specialized knowledge required for certain identification of the various ceramic ingredients.

When, therefore, Miss Shepard, a trained petrographer, began the study of ceramic technology, she entered a practically virgin field. Her work on ancient Pueblo pottery quickly demonstrated its value in permitting more accurate and more objective description of wares. She has also often been able to recognize in pottery mineral inclusions not found in local deposits and, by identifying their source, has not only proved the vessels in question to be trade pieces, but has in many cases been able to determine their place of origin. This is obviously of the greatest importance to the archaeologist.

Miss Shepard, through cooperation of the Laboratory of Anthropology at Santa Fe, has for several years taken part in the Institution's studies of Southwestern and Maya pottery. On January 1, 1936, she joined the Division staff on temporary appointment. She has continued her research upon the collections of E. H. Morris from the La Plata region of northwestern New Mexico, and upon those of J.E.S. Thompson from British Honduras. During the past winter, she spent six weeks in Guatemala studying, with R. E. Smith, the wares of Uaxactún. An unexpected result of Miss Shepard's Maya work has been the discovery that a large percentage of the pottery from British Honduras, from Uaxactún, and even from northern Yucatán contains tuff temper, although no deposits of this material are presumably to be found within long distances of the sites producing the vessels. The pottery neverthe-

less appears to be of local manufacture. This raises problems of the extent and direction of aboriginal trade in raw materials, whose solution will throw much light upon prehistoric conditions in the Maya area.

4.5.

ANNA O. SHEPARD

Ceramic Technology

YB 37:159–161, 1938

The plan of the Ceramic Technology Project has been to conduct concurrently studies of both Maya and Anasazi (Basket Maker-Pueblo) pottery. This division of effort is advisable because the archaeological investigations of the Division are being conducted both in the Maya field and in southwestern United States, and also because a greater diversity of materials and problems is thus presented. The methods of pottery making in the two areas are in many ways distinct and the course of ceramic development differed. A broader knowledge of primitive techniques is therefore gained; and, at the same time, opportunity is afforded to work out the evidence of culture contacts and influences as shown by trade in pottery and spread of specialized techniques of pottery making at two levels of cultural development. The purpose of the technological laboratory is to make extensive and systematic investigations which may be expected to yield data of general historical interest, rather than to provide facilities for analyses to be used for miscellaneous and unrelated identifications. Cooperative studies with other institutions are therefore made only when material contributes to the solution of the broad problems outlined for investigation.

Research in the Maya field during the year centered mainly around the completion of technological notes on the pottery of San José, British Honduras, for Mr. Thompson's report on this site. The various pastes had in the main been identified the previous year, but more detailed studies and comparisons with pottery from Uaxactún showed definite possibilities of tracing to their source a portion of the limestone-tempered pastes which are so widely distributed in the lowland region. The tuff-tempered wares regarded as intrusive in San José were re-examined for comparison of properties of the tuff with that in pottery from Copán, San Agustín Acasaguastlán, Kaminaljuyú, and Zacualpa. The study of San José pastes was supplemented by the

microscopic examination of sherds from Holmul, Tayasal, and Baking Pot in the Peabody Museum at Harvard. As the paste of over 1,400 sherds was identified, our knowledge of the distribution of tuff-tempered wares in the lowland region, a phenomenon of primary interest because of the questions of trade which it raises, was extended; and the necessity of considering frequency of occurrence in relation to natural resources was demonstrated. The marked differences in the proportion of tuff temper, both by period and by ware, in the various sites shows that distribution and relations are complex. Extensive studies will accordingly be necessary in order to determine the full significance of the numerous occurrences of tuff-tempered pottery in the limestone area.

Maya potters gave especial attention to vessel finish; and brightly colored, highly lustrous surfaces are characteristic of the monochrome slipped wares of the Petén. The properties of these slips indicate the use of specialized techniques which should provide important clues for study of the spread of traits. A number of different experiments were made to determine whether or not these surfaces were coated with some organic material after firing and the effect of such material, if present, on luster and color. Some positive evidence was obtained and a number of problems outlined for future investigation.

The principal advance made in the Ceramic Technology Project during the year was in extending the scope of the work to include chemical analysis. Simple qualitative tests and a few quantitative determinations had previously been carried out, but adequate facilities for chemical analysis were not available until the project was moved to Boulder in October. A laboratory was then equipped and the essential apparatus for micro-qualitative and micro-quantitative analyses obtained. Basic training in analytical chemistry and micro-technique was taken by Miss Shepard during the year while devoting full time to her regular duties.

4.6.

ALFRED V. KIDDER

Ceramic Technology

YB 38:246–248, 1939

During the current year studies in ceramic technology by Miss Shepard were continued in both the Maya

and the Southwestern fields; those in the Maya field were devoted largely to the Uaxactún collection and to general analyses of a preliminary nature, and those in the Southwestern field to specific problems outlined by earlier investigations, particularly firing methods, and paste composition of Río Grande glaze wares.

The study of Maya pottery presents serious difficulties resulting on the one hand from limited knowledge of the distribution of types with consequent uncertainty regarding the source of foreign sherds, and on the other from the nature of the pottery itself, for both peculiar and ill-understood methods of manufacture and the extreme weathering which characterizes much of the material from sites in the tropics makes accurate identification by visual inspection alone almost impossible. There are therefore decided advantages in introducing microscopic and other methods of analysis at the very inception of ceramic studies, as a means of ascertaining how peculiar effects in finish and decoration were obtained; while paste composition, which may constitute a basic criterion of classification, can always be accurately identified even in badly weathered material. Thus technological analysis furnished a sound basis for classification, as well giving independent evidence bear upon the relations of types and their sources. With these objects in view, pottery from sites excavated by the Division is being studied and the material supplemented by that from other collections, in order to build up our knowledge of the distribution of techniques and materials. In the fall a petrographic study was made of the principal pottery types of Uaxactún and of a representative series of sherds from Copán, 178 thin sections having been prepared and analyzed. This work brings the collection of thin sections of Maya pottery to 655, including material from Petén sites, the highlands, Copán, and Chichén Itzá. In addition to petrographic work, the sherd collection from Benque Viejo, British Honduras, was studied with the binocular microscope, paste composition and surface finish being compared with that of pottery from San José, British Honduras and Uaxactún.

In the spring Miss Shepard spent two months in Guatemala in work on the Uaxactún collection. A total of over 10,000 sherds from stratigraphic tests was examined, and the tempering materials used in the various periods and areas are therefore now fully defined. The three main classes of tempering material (sherd, calcite, and tuff) which occur in the principal pottery types show a clear-cut chronological sequence and definite correlation with style and form. There is therefore every indication that temper will be an important means of learning sources of influence and the origins of imported pottery when distributions are better known. The value of the microscope for identifying

intrusives, especially when surfaces are weathered, has also been fully demonstrated. Yucatán Slate Ware and Eggshell Orange from Mexico were both identified in this way. In addition to the analysis of paste composition, attention was also given to problems of surface finish and a microscopic study was made of pigments of polychrome vessels. Certain pigments, particularly browns, grays, two flesh colors, pink, and purple, were found to be mixtures of basic pigments. This study will be carried farther to determine what extent particular colors and color techniques characterize pottery types and districts of manufacture.

Ten days were spent at Copán in the study of sherds obtained from stratigraphic tests. The basis of classification of this material was checked and a preliminary analysis made of paste and finish. A search was made for local sources of clay and temper, and samples of raw materials were collected for laboratory testing.

4.7.

GEORGE W. BRAINERD
Study of Yucatecan Pottery

YB 39:270–274, 1940

The purpose of the study now under way, is the establishment of a correlated sequence of the prehistoric pottery types of Yucatán order to discover what chronological cultural interrelations existed among archaeological sites.

Such a chronological scale is, of course, of prime importance in providing the historical framework to which the archaeology of any area must be fitted. Although epigraphy has furnished us with the basis of our chronology, the absolute dates thus obtained can necessarily serve only as anchoring points for a detailed cultural history. Yucatecan sites have no dated monuments, and when sculptured dates do occur the difficulty of associating them closely with structures and artifacts is often insurmountable. Pottery provides the easiest and most reliable method available for the exact placing of cultural material in the time scale.

It is probable that a careful study of Yucatecan pottery will uncover data of much more general significance in Maya archaeology than the simple filling-in of dates on a calendar outlined by epigraphic evidence. Although Yucatán is peripheral to the main

Central American cultural stream, the importance of its chronology is enhanced by the fact the correlation between the Christian Maya calendars (upon which all exact datings depend) is based upon Spanish records made in Yucatán at the time of the conquest. Owing to the abbreviated method of writing dates used by the later Yucatecan Maya, there is a period of unknown between the last inscriptions written in the unabbreviated older style and the date of conquest. Therefore, a pottery chronology correlated with the abbreviated hieroglyphic dates, reaching from the conquest to any of the Old Empire style dates, is needed.

The materials available for the study consist of pottery collections from some 30 sites in the Yucatán peninsula which have been made by various Carnegie Institution workers during the past 16 years. They consist of a few whole vessels, and about 200,000 sherds selected from excavated collections of perhaps eight times that number of fragments. The bulk of the pottery comes from the extensive excavations carried on at Chichén Itzá. Most of this material was obtained as a by-product of the excavation and restoration of buildings, although some was taken from special trenches cut into dumps. Test samples from most of the other sites represented were obtained by H. B. Roberts during four field seasons, spent chiefly in the Puuc region in the western part of the peninsula, in conjunction with the architectural survey of this region conducted by H.E.D. Pollock. This joint survey was arranged in the hope that the cross-correlation of architectural and ceramic traits would give a rounded picture of the sites visited. The pottery survey was, however, interrupted by the illness and subsequent resignation of Mr. Roberts.

Dr. George C. Vaillant formed some tentative theories as to Yucatecan pottery chronology in 1927 from a study of the whole vessels available in museums, and in 1929 he worked out a partial Chichén Itzá chronology from trenches in the court of the Temple of the Phalli. At Holmul (which actually does not belong in this region) a pottery sequence was determined, chiefly however from ornate burial pottery which cannot be correlated with the pottery normally found in excavation. Other than these isolated studies, no chronological pottery work has been reported upon.

The following sites were represented in the Carnegie collections stored at Chichén Itzá: Calakmul, Cobá, Holactún, Oxkintok, Uxmal, Chacbolai, Chacmultún, Chunchuhub, Dzibilnocac, Dzibiltún, Chichén Itzá, El Palmar, Labná, Santa Rosa Xtampak, Yaxuná, Kabah, Kewic, Nohcacab, Nocuchich, Hochob, Huntichmul, Iturbide, Itzimté, Sabacché, Sayil, Tabasqueño, and Xlabpak-Maler.

Dr. Brainerd began this work without previous experience with Central American pottery, but with

archaeological experience in Iran, northern Arizona, and Tennessee, and a total of about three years' intensive laboratory work on Arizona pottery carried on for the most part at the Ceramic School of the Ohio State University. Therefore, although methods of dating by means of potsherds were well known to him, a period of study of the new type of material was felt necessary. At the beginning of this project in December 1939, six weeks were spent at the laboratory of Miss A. O. Shepard in sorting and microscopic examination of sample collections of Yucatecan sherd material.

After this work and after study of Roberts' field notes, Dr. Brainerd went to Chichén Itzá to begin detailed study of the collections. The work in Yucatán has thus far consisted almost entirely of classification and description, the building-up of the corpus from which the results will be drawn. A week was spent in excavating pottery samples, totaling several thousand sherds, at Oxkintok, where an early date had recently been discovered. Three weeks were spent with Mr. R. E. Smith in the location of Petén types of pottery in the collection, and in the discussion of methods for Maya pottery classification. Owing to the deterioration of labels caused by 4 years' dead storage in so humid a climate, considerable reorganization and relabeling was necessary. To minimize further deterioration, and to prevent confusion in the extensive sherd comparisons now being made, the majority of the sherds have been printed individually with their provenience. The collection has also been indexed and moved to Mérida, where it is now permanently housed. During the time consumed by the move, 600 photographs of pottery were taken in private and museum collections at Mérida, for the purpose of comparison and as an aid to the reconstruction of whole vessels from the sherds in the Carnegie collection.

Although the study has not reached the stage of interpretation, a tentative statement of the developments as they now appear may be made. The work was begun on material from Cobá and continued with that from Yaxuná, Calakmul, and various Puuc sites, on the theory that the best understanding could be reached by following a sequence from early to late, based on available site datings. Chichén Itzá was left until last. Its location is somewhat isolated, making it not essential to the Puuc chronology, and it was felt that its comparative complexity could be better unraveled if the chronologies of related regions were built up first.

The Cobá sherds were easily divided into two groups: one of finely made, and quite varied pottery; the other all made of a very coarse calcite-tempered paste, some pieces slipped and some unslipped. In the deepest trench the fine ware is much more common at the bottom of the deposit, which seems to have antedated the plaza floor upon which the nearby build-

ings stand. According to Mr. Smith, who examined the pottery, the fine ware is in large part analogous with Old Empire wares found at Uaxactún. The coarse ware bears a general resemblance to the San José pottery illustrated by Thompson, although there are minor, constant differences. Interestingly enough, there are only 27 fragments of the slateware so abundant in many other Yucatecan sites. These were scattered through the tabulated sample of 2,338 sherds, about one percent. The two possible explanations of this scarcity are that the Cobá deposit in question precedes the body of Yucatecan sites, and that slateware was not made in or often traded to that part of the peninsula. Fifteen sherds containing a considerable proportion of finely divided cellular material, seemingly plant stalks, were found well scattered through the trenches. They all came from similarly shaped vessels. Miss Shepard, to whom a sample was sent, reports that she has not examined pottery similar to this. The presence of a type of temper differing so widely from the mineral tempers characteristic of the Maya area suggests the possibility of foreign cultural contacts on the east coast of the peninsula.

The collection from Yaxuná is very small (272 sherds). Since no qualitative differences could be seen in the sherds, they were tabulated together. Over 50 percent of the material consists of slateware, a proportion close to that found in the Puuc material so far examined, although the shapes are somewhat different. There are two types of coarse, unslipped, calcite-tempered, jar rims, one of which is more suggestive of the corresponding material from Calakmul than of that from any other site in the collection. Mr. Smith classifies several of these rims as early Old Empire Petén types. Red-Slipped Coarse Ware is present in Yaxuná as at Cobá but in smaller proportion. Fine, thin-walled monochrome and polychrome wares, markedly different from the above material, constitute about 15 percent of the sherds. Smith identified various sherds from the Yaxuná series as belonging to pre-Old Empire and Old Empire Petén types, but the present collection is too small and mixed to allow of its correlation by individual samples with the distinct Yucatecan wares present. More excavation is obviously required to clarify this situation. The results might well justify such excavation. The large time range represented by the relatively abundant Petén-style material should give valuable checks of the sort needed for correlations with epigraphic material if pottery deposits of sufficient size can be located.

A collection from Calakmul was examined and tabulated. It had been gathered during work upon stelae and came from the fill which had fallen against the monuments as a result of the collapse of adjacent structures. Hence the suggestion is that the pottery is older

than the stelae, although this may not be so. Smith classified most of this pottery as late Old Empire, and considers it to vary only slightly from Uaxactún material. A large proportion of the slips on coarser vessels from Calakmul shows the translucency and waxiness of the slips of slateware, which is present in very small percentages, if at all, at Uaxactún. Their colors are generally deeper than the dull buff or gray most common in Yucatecan pottery. It seems possible that there may be some intergrading of slateware with Petén types.

The material from Oxkintok, where an almost certainly early date (9.2.0.0.0) has been found, was excavated in the hope that early pottery from the Puuc area would be forthcoming. Fortunately there was found a deposit 2.5 m deep containing a seemingly homogeneous mass of pottery overlaid by nearly sterile earth. In the top of this trench, as well as in three others, pottery comparing closely with that from other Puuc sites was found. The earlier pottery includes no slateware, and it is in other ways quite different from any other in the Yucatán collections. Mr. Smith was also unable to place it. Much of it has a slip averaging light ochraceous buff to cinnamon, applied over a slightly granular surface. The vessel shapes are highly diagnostic; one of them, a basin with sub-rim flange, is reminiscent of the coarse, red slipped basins of Cobá, as is the general scale and texture of the whole ware. It seems likely that the affiliations of this pottery will be found in early sites somewhere to the southwest of the peninsula. At present there are no such sherds for comparison.

In the Kabah collections Mr. Smith found sherds which he equates with nearly the whole range of Uaxactún ceramics. He also noted slateware in shapes characteristic of Uaxactún. These findings, of course, suggest a long occupational sequence which might be tied in with the Petén. Unfortunately a listing of his identified sherds shows them to be distributed so haphazardly through trenches and levels that a chronological rating of the trenches is impossible. The local wares also have not suggested any stratigraphy as yet, although a complete tabulation was made for all trenches. The sample is rather small (1,244 sherds); more excavation might help in the correlation, particularly if large, homogeneous deposits could be found.

The collections from Uxmal are large and contain material of a very high grade. Their homogeneity, as well as their lack of Petén resemblances, suggests an extensive and late occupation. The larger collections, from the site have been tabulated, several show good stratigraphy, although the changes are in percentages of types rather than in the types themselves. The lower levels of several of the trenches at Uxmal yield specimens corresponding closely to materials from Kabah,

while the upper levels do not. More definite comparisons between the tabulations should allow closer correlation between the two sites.

It seems evident from the Puuc materials examined that few definite qualitative criteria exist between sites, and that correlations and datings must depend upon close statistical work and perhaps upon mineralogic differences between potteries made at different sites.

The Chichén Itzá pottery has not yet been tabulated, although considerable time has been spent in its organization. From cursory examination it seems evident that for the most part it is quite distinct from the pottery thus far worked. The determination of its chronology should be considerably helped by the architectural evidence accompanying the pottery, by the large size of the samples, and by the system evolved during the handling of the other collections.

The above observations have been made previous to a general, systematic comparison of all the material. Later work may confirm or refute them, and will indubitably add others. The final goal of the study, a chronological scale, can be reached of course only upon the close intercorrelation of all material, which will be the final step of the present work.

At present the establishment of a Puuc chronology seems certain, although the number of stages and dating criteria which it will comprise is not yet evident. Owing to Mr. Smith's examination of the collection, we now know that a considerable quantity of Petén-style pottery is present, and it is possible that technological analysis will prove whether such pottery is imported or locally made. The presence of early Petén pottery in the badly mixed deposits dug at Kabah suggests that more excavation might yield material for the Old Empire chronological check. The newly discovered complex at Oxkintok, of which we have a large sample, may prove to be the first step in the discovery of the time and route of Maya colonization in western Yucatán.

The pottery of Cobá substantiates the epigraphic and architectural evidence of its Old Empire and East Coast affiliations, and suggests that further work might produce Puuc dating correlations. The samples from Yaxuná indicate much closer connection with the Puuc than with Cobá, although a moderate percentage of the Cobá material is present. Actually, Yaxuná is closer to Puuc sites than to Cobá, a fact which the presence of the Cobá-Yaxuná causeway has tended to obscure. The finding of early Uaxactún-like pottery adds another argument for further excavation at Yaxuná, in the hope of closer Old Empire chronological correlations. There is every evidence that Kabah would also yield material interlocking with a long period of Petén chronology, and the size and condition of the ruin perhaps make it

a better possibility than Yaxuná for obtaining such material.

Chichén Itzá remains as the likely source of much information which still eludes us. Its long occupation coupled with its median position in the peninsula should allow it to serve as a connecting link among the various isolated samples from widely separated sites. The collections are large, and the material varies widely. The results should be rich.

4.8.

ANNA O. SHEPARD

Ceramic Technology

YB 39:275–277, 1940

Systematic work on the microchemical analysis of ceramic materials was undertaken during the current year for the first time. The desirability of obtaining chemical analyses, quantitative as well as qualitative, of paints and glazes, and also of certain classes of slips and tempering materials, has been recognized from the start, but this field has been neglected partly because of the extreme limitation in quantity of material obtainable, which greatly increases the difficulty of analysis, and partly because results of petrographic analysis have proved so fruitful that full time has been required for meeting the archaeologists' demands. Therefore only a relatively few simple qualitative microchemical tests have been used. During the past year a part-time student assistant handled routine work required for petrographic analysis, freeing more time for basic research on new methods.

The application of chemical methods in pottery analysis requires much more preliminary experimentation than does the use of petrographic methods. We can use with very little modification the techniques which the geologist has employed for many years, whereas in the case of chemical analysis we are borrowing from the relatively new but very rich field of microanalysis, and our samples and requirements differ from those for which the methods were developed, so that each procedure must be thoroughly tested and often considerably modified. Quantitative determinations on samples as small as those which are obtainable from the pigments of pottery present such serious difficulty that until recently they have rarely been at-

tempted by the chemist. Our laboratory is equipped with a microbalance (weighing to 0.000002 g), without which quantitative work would be impossible, a photoelectric colorimeter, and a microelectrolytic apparatus, all of which greatly facilitate the work. During the summer of 1939 the assistance of Mr. F. G. Schoffman, of the Chemistry Department of the University of Colorado, was obtained, and methods for quantitative determination on 3-mg. samples of eight of the elements most commonly found in ceramic materials were tested and applied. Gravimetric, volumetric, electrolytic, and colorimetric methods were used. In this preliminary work, in order to test the methods and also to test the value of the chemical data from the archaeologists' point of view, samples of 28 Pueblo glaze paints were analyzed quantitatively for from two to eight elements. Glaze paints were selected for analysis because the geographic distribution and sequence of types is sufficiently well known to permit the formulation of specific questions regarding trade, and direct influence on, and independent developments in, technique. Comparable material is not available at present from the Maya area. The results showed, first, that it is possible, and practicable to make quantitative determination on 3-mg. samples with an accuracy well within the limits required by the nature of our materials; second, that the results of such analyses have archaeological significance and enable us to answer directly questions which would otherwise remain subjects of speculation; third, that quantitative as well as qualitative analysis is necessary satisfactorily to answer these questions.

During the fall and spring microchemical work was continued with the analysis of three classes of Maya ceramic materials: iron manganese paint, carbonate tempers, and clay slips. Quantitative determinations of iron and manganese were made on the paints by rapid colorimetric methods to learn whether or not the ratio of the two major constituents might distinguish ores from different deposits. The painted wares on which this kind of pigment occurs are as yet ill defined, and little is known of their origin and relationships.

Similarities or differences in paint should help clarify these questions. The quantitative methods developed are rapid and accurate, and preliminary results showed a wide variation in ratios, and some indication of correlation with pottery types.

The carbonate tempers were studied in order to find a simple field test to distinguish dolomite or, dolomitic limestone, from magnesium-free limestone. Carbonate tempers were used in such a large proportion of Petén pottery that it is desirable to distinguish varieties of this temper in order to use temper as a means of locating sources or distinguishing wares from different sources. So far dolomite and dolomitic

limestone have been found in distinctive pottery types, but we have lacked a satisfactory field method for rapid identification dolomite. Four organic reagents for magnesium were studied, and their sensitivity and the limiting proportions of interfering ions were tested. One reagent, Titan Yellow, was found satisfactory for field use.

A number of Maya pottery types are characterized by slips having peculiar properties; for example, the exceptional luster and brightness of color of Petén Orange and Red and the hardness, vitreous appearance, and iridescence of Plumbate Ware. It was thought that chemical analysis of major constituents, particularly silica, alumina, and iron, might indicate whether or not an unusual type of clay was used, and aid in explaining the properties. The composition of the surface material of Plumbate, an important ware in Middle America because of its wide distribution and definite chronological position, was of particular interest because it was not definitely known that the surface had a clay slip and the nature of this surface has long been a puzzle to archaeologists. The microquantitative determination of silica in 3 mg samples proved difficult, and a number of procedures were tested before satisfactory results finally obtained by using a platinum filter stick to avoid transfers. Three Petén samples and seven from Plumbate and Plumbate-like sherds were analyzed. The results showed that Plumbate Ware has a slip of claylike material, and the proportion of element determined, sheds light on the peculiar properties of the surface.

Opportunity was afforded through a special grant to test the applicability and value of spectrographic analysis of the materials which were being tested microchemically. We were especially fortunate to have the analyses made at Massachusetts Institute of Technology under the direction of Dr. G. R. Harrison. Two hundred and six samples were analyzed, including glaze paints, iron manganese paint clay slips, and miscellaneous pigments from Kaminaljuyú. Results proved the value of method for rapid qualitative identification and especially for the detection of trace elements which could not be identified by another means. Trace elements no less than the ratios of major constituents may serve to distinguish material by source. Encouraging results were obtained with the Petén slips, but in the Pueblo glaze paints the proportion of major constituents appears more significant than the trace elements. Some quantitative spectrographic determinations were made of iron manganese ratios, but considerable research will be necessary before this procedure can be generally applied.

The collection of samples no less than the method of analysis presents serious problems. From one to two hours were required to obtain by delicate scraping most

of the samples analyzed. The process must be observed with the binocular microscope to avoid inclusion of clay with the paint, and the risk of contamination is too great to entrust the work to an assistant.

During the fall approximately a month was spent in a final check of pottery from Benque Viejo, British Honduras, for Mr. Thompson's report on this site. From November through early January laboratory facilities were made available to Dr. G. W. Brainerd, and assistance was given him in his preparation for work on Yucatecan pottery.

Petrographic studies were facilitated by the part-time assistance, from October through the rest of the year, of Mr. R. Spangler, senior in geology at the University of Colorado. Mr. Spangler, after training, prepared 674 thin sections. Sherds from Uaxactún, Zacualpa, Kaminaljuyú, Miraflores, and San Agustín were sectioned. Mr. Spangler was also trained in the use of the binocular microscope for temper identification, and identified temper in a large collection of stratigraphic test sherds from a Río Grande site, through the courtesy of the Museum of New Mexico. The study is an extension of that started with Pecos pottery for Dr. Kidder at the inception of the Ceramic Technology Project. Finally, Mr. Spangler was directed in the study of a collection of miscellaneous materials from Uaxactún, including mortars and plaster, and materials from vessel interiors. A different approach was made in the study of plasters from that usually followed. Chemical analysis, because of the nature of the processes taking place in the calcination, slaking, and subsequent exposure of limestone plasters, does not show whether or not they were calcined; therefore, for the Uaxactún samples, chemical and mechanical separations were made and the residues and fractions studied microscopically. In this way indirect evidence of calcination of some of the plaster, and of the use of some unburned limestone, was obtained. The microscopic features of the residues were so distinctive that they gave promise of the possibility of identifying limestones from different quarries.

The principal petrographic work undertaken during the year was the study of pottery from the Guatemalan highlands, including a comparison of paste types of a western, highland site, Tajumulco (material lent through the courtesy of the Museum of New Mexico), and southern highland pottery. A special study of Plumbate pottery from the highlands, Salvador, and Chichén Itzá was made. Petrographic evidence gives promise of throwing light on the place of origin of this important ware.

4.9.

ANNA O. SHEPARD
Ceramic Technology

YB 40:302–304, 1941

Ceramic technological investigations for the current year have included a statistical digest and final check of data on Río Grande glaze-paint pottery, a study of Plumbate Ware from highland sites in Guatemala, petrographic analysis of fragments of tomb vessels from Kaminaljuyú, Guatemala, and temper identification of the collection of Yucatecan sherds in Mérida.

The study of glaze-paint ware was undertaken mainly to clarify and illustrate the place of technological analysis in ceramic archaeological research. Pueblo rather than Maya pottery was chosen as the basis for a critical evaluation of the results of such analysis because the frame work of Pueblo archaeology is better known than is that of the Maya. In particular the distribution of pottery types and their time relations, have been traced in considerable detail in the Southwest. Also important to the study was the fact that, information on geological formations and natural occurrences of ceramic materials is more easily obtained for the Southwest than for Central America. As long as archaeological research is in the stage of reconnaissance, in which the mapping of distributions forms a major activity, there is a tendency to limit laboratory analysis of pottery to routine identification. Not until there have accumulated the basic data from which specific problems regarding cultural development and relationships can be outlined, is it possible to utilize fully and effectively the facilities for exact identification which ceramic technology offers. The statistical summary of the technological data on glaze-paint ware shows how composition of paste and paint provide specific evidence regarding the area in which the ware was made, the principal centers of its production, and the extent to which it was traded. These are questions which hitherto have been only subjects for speculation. Likewise the study has shown the importance of correlating stylistic and technological evidence, particularly in instances where there has been mixture of local varieties of pottery through trade. The manuscript which is now completed, was written in the hope that a striking illustration of the importance of proper sampling, specific and exact identifications, and complete correlation of technological and stylistic data would enable the archaeologist better to judge the type of problem for which technological analysis can effectively be employed, and prevent the waste of time often involved in making meaningless analyses.

The petrographic analysis of Plumbate Ware has been continued in order to accumulate evidence bearing on the place of manufacture of this type of pottery, which is of outstanding archaeological importance because of its wide distribution in Middle America. Theories which have previously been advanced regarding its origin have been based principally on the geographic distribution of the ware, and on its stylistic affinities. Information regarding distribution has been gained in considerable part from local collections and is therefore not only incomplete but also possibly misleading. In consequence both Salvador and the highlands of Guatemala have been seriously proposed as the source of the ware, and in each case the arguments are based on supposed frequency of occurrence. Mexican traits are noticeable in vessel shapes, in Tlaloc effigies, and in motives of incised design. These features, however, give us no means of ascertaining how far into Central America the Mexican influence may have penetrated. The composition of the paste of the ware offers more specific information. For many years the hope has been harbored that the particular kind of clay from which Plumbate Ware was made might be found. A direct search for the clay would be impracticable, and the chances of obtaining ethnological leads from the survival of tradition regarding the ware are practically negligible. The evidence of composition, which at present seems most promising, is of quite a different nature. Plumbate Ware contains very fine tempering material which consists of mineral grains and glassy rock fragments. All Plumbate sherds which have been analyzed (including specimens from Salvador; from San Agustín Acasaguastlán, Zacualpa, Tajumulco, and El Quiché in Guatemala; and from Chichén Itzá in Yucatán) contain this same kind of temper. If identical temper should be found in the common wares indigenous to a site where Plumbate Ware was abundant, we should have circumstantial evidence regarding the place of manufacture of Plumbate. Pottery from Tajumulco, a site in the northwest highlands, excavated under the auspices of the Museum of New Mexico, has been studied in detail because of the considerable number of sherds in the collection having the appearance of unsuccessfully fired Plumbates. The petrographic analysis of sherds from this site revealed, for the first time, temper similar to that of Plumbate in sherds of non-Plumbate style. It would be premature to conclude from this occurrence that Tajumulco was a place of manufacture of Plumbate Ware, because only a relatively small number of sherds were brought out from the site and made available for study. It is, therefore, possible that the Plumbate sherds and also the few non-Plumbate sherds with similar temper are intrusive in the site. Nevertheless a very promising means of locat-

ing the place of manufacture of Plumbate Ware has been recognized.

The surface finish of Plumbate Ware is no less distinctive than its shape and decoration, for it is unique in American Indian pottery. The peculiar range of colors and glaze-like luster have long attracted and puzzled the archaeologist; microscopic examination and chemical analysis reveal properties which, though less obvious, are no less unusual and interesting. The work completed to date has conclusively disproved a fallacy which has long persisted in the literature, the supposition that the material was a lead glaze. Analysis has shown that the lustrous material is basically a claylike substance which was applied as a slip. This disproves a second fallacy, the supposition that the surface and body were both the same, or that the surface layer was produced as an exudation of material from the body. Studies are being continued on the crystalline structure of the surface coat, its firing properties, the cause of its luster, and the technique of application.

During the fall, a month was spent in Mexico, two weeks being devoted to identification, with the binocular microscope, of temper in the collection of Yucatecan sherds at Mérida. The primary object of the study was to aid in the classification and description of the pottery, undertaken by Dr. Brainerd. The variety of materials found and their distribution, however, also indicated that paste composition will, here as elsewhere, give evidence of sources of types and the extent of trade in them, when adequate samples are made available for study.

A series of 65 fragments from Kaminaljuyú tomb vessels was analyzed petrographically for purposes of record and evidence of source. Since the great majority of pastes contained material of volcanic origin, either vitric or crystal tuff, it was necessary to make a detailed study of all features which might distinguish tuff from different localities. Particular attention was given to the structure of the tuff and the heavy minerals. As a result of the analysis a few vessels were clearly indicated as intrusive, but the temper of the majority was of the type common in the Guatemala highlands. A small collection of sherds of cylindrical tripod vessels from Teotihuacán, loaned by the American Museum of Natural History through the courtesy of Dr. Vaillant, were sectioned and the paste compared with that of cylindrical tripods from Kaminaljuyú. Although the tempers in both sites are of volcanic origin, they are readily distinguished in thin section. On the other hand, identity of the paste of Thin Orange Ware from the two sites proved that the vessels represented were all from same source. During the summer of 1940 courses in theoretical and applied spectroscopy and colloid chemistry were taken at Massachusetts Institute of Technology. Emission spectroscopy offers the

most practicable method for complete qualitative analysis of small samples, and the only method for determining trace elements in such samples. It is therefore a valuable means for analyzing paints and slips. The course in colloid chemistry covered fundamentals which contribute to an understanding of the properties of clay and also of many characteristics of primitive pottery.

4.10.

GEORGE W. BRAINERD

Yucatán: Pottery

YB 41:253–257, 1942

The present study of Yucatecan ceramics was begun in December 1939. The year 1940 was spent in Yucatán in the classification, tabulation, and illustration of the extensive sherd collections gathered during the previous work of the Institution [Chapter 4.7]; 1941 in Cambridge in making chronological studies from previous notes, in comparative work on museum and published material, and in preparation of the material for publication.

The analysis of the pottery collections showed that an overwhelming percentage of these belong to two major periods, neither of which can be accurately dated in either the Christian or the Maya calendar, and which together represent the relatively short part of the span of human occupation in the Yucatán peninsula characterized by the building of the more imposing of the standing architecture. The two major periods represented in the material excavated previous to this study can be identified with 1. the major buildings in ruins of the so-called Puuc region, Sayil, Labná, Kabah, and Uxmal, and the earlier buildings at Chichén Itzá; and 2. the later, or "Mexican," buildings at Chichén Itzá. These periods will be called "Puuc" and "Mexican" respectively for ease of reference. In addition to these main groups, pottery referable to all the Petén periods was represented in various collections but without definite stratigraphic association with the native pottery. At Chichén Itzá there were stratigraphic evidences of a later ceramic period, the pottery of which equate with isolated fragments and specimens from widely separated localities in Yucatán. A considerable number of distinctive groups of fragments occur in collections which could not be placed chronologically from

the collections on hand last year. The collections made from Oxkintok in 1940 produced a large sample of pottery stratigraphically proved to antedate the Puuc period and inferentially associated with the earlier style of Oxkintok architecture (Shook 1940), in which a lintel dated 9.2.0.0.0 was found.

This year's program was planned to supplement the available material to such an extent that a general chronological sequence, including the total span of pottery making on the peninsula, could be built up and its major periods described. It was also hoped that the completion of such a span would allow it to be dated with regard to the Maya calendar, the Christian calendar, or both, thus furnishing material to aid in the correlation of the two calendars.

The field work during the present season has consisted of five trips which together occupied approximately three months. Each group of ruins investigated was sampled by 10 to 20 trenches distributed throughout the site. From one to five of these were usually found to contain large stratified deposits, the analysis of which served as the key by which the other collections from the site could be identified. The best sources of large, stratified deposits proved to be cenotes whenever these were present near the ruin. Since the end of the field trips the greater part of the collections has been classified and tabulated, and illustrations have been prepared for about half the material. Mr. R. E. Smith spent several days in Mérida in the examination of this year's collections, making available to the study his thorough knowledge of Petén pottery typology. The tentative results, thus far obtained will here be presented in the order of excavation.

Yaxuná was visited. A previous sample excavated from this site, though small, shows a large variety of pottery types and considerable Petén contact. The larger collections obtained on this trip permit the definition of four distinct periods, characterized by changes in the basic wares. The first period can be equated definitely with the pre-Old Empire period in the Petén. The second seems to equate with early Tzakol in the Uaxactún chronology, but stylistically shows closer similarities to Early Ticoman pottery of the Mexican highlands. The third period appears to have been contemporaneous with later Tzakol and Tepeu 1 at Uaxactún. The last period equates with the pottery of the Puuc, or the earlier great building period at Chichén. A sculptured stela and a sculptured jamb were found and notes, drawings, and photographs made. Additional mapping was done on the site. Work of this sort was conducted at each site visited, including sufficient mapping to locate all pottery trenches accurately.

The site of Dzibilchaltún has not previously been reported upon. It lies 1 km south of the hacienda of the

same name, and about 15 km north of Mérida. It consists of an aguada with a nearby ruined colonial church standing in the center of a Maya plaza. The site was suggested by Professor Alfredo Barrera Vásquez as a likely source of early colonial pottery. In addition to such pottery, several large groups of ruins, two partially standing Maya buildings, about 2 km of causeways, and 22 stelae (six of which were sculptured) were discovered and mapped. Measured drawings were made of the Spanish buildings, and of remains of frescoes in the church. At one of the buildings a dubious sculptured date of 1593 was found, which, however, is given some support by a date of 1617 discovered at the architecturally similar church of the neighboring village of Chablekal. Mr. E. W. Andrews took notes on the Maya architecture and stelae, including plans and sections of the two standing buildings. The pottery from the Maya ruins consists of a small collection of pre-Old Empire sherds, a large collection which seems immediately to antedate the pottery from the Puuc area, and a small collection of a period contemporaneous with the Mexican period at Chichén Itzá.

At Acanceh the best sherd collections obtained came from the base of the pyramid which is surmounted by the building bearing the well known stucco façade (Seler 1911). The collections have not been sorted as yet, but are known to contain material ranging from pre-Old Empire times through the Mexican period. The pottery resulting from Mr. Andrews' clearing of the buildings surmounting the pyramid may allow these buildings to be fitted into the ceramic succession. A preliminary check of the material indicates that collections deposited after construction of the building with stucco façade antedate the Puuc period.

A large quantity of pottery was excavated from Mayapán, and a collection was obtained from the cenote of the nearby town of Telchaquillo. The Telchaquillo pottery is all post-conquest. The Mayapán collection contains small groups of pre-Old Empire and Old Empire Petén, and of Puuc period pottery from the bottom of a trench sunk in the mouth of a cenote. Above this shallow deposit, pottery of the Mexican period of Chichén occurred mixed with, and finally superseded by a deep deposit of redware of later date. A series of trenches dug near buildings throughout the main group of the ruin produced collections in which late redware preponderates. Several of the buildings have since been cleared and mapped by Mr. Andrews. The redware found at Mayapán corresponds to redware of the latest occupation of Chichén Itzá, an occupation which at the latter site left little pottery and few if any architectural remains. The Mayapán deposits contain a Fine Orange Ware which is stylistically the immedi-

ate descendant of the "X" type Fine Orange found at Chichén Itzá (Brainerd 1941).

The final field trip of the season was made to Ticul, Dzan, and Maní. Modern pottery making was studied at Ticul, and excavations were made in the environs of the three towns. Classification of the extensive collections made is as yet incomplete. The town cenote at Maní yielded a sequence ranging from a horizon to which we have thus far recognized no affiliations: through pre-Old Empire, through the Puuc and later periods, into heavy postconquest deposits. Deposits on the grounds of the historic Maní church and monastery present an extensive Spanish colonial sequence, ranging from vessels closely related in form and ornament to Dzibilchaltún specimens, up to modern times. These collections are rich in Mexican and European glazed wares, and we hope for accurate dating of the associated native wares from this part of the sample. Other excavations chiefly in chultuns in Dzan and Maní and near Ticul yielded samples of the Mexican, Puuc, and later redware periods, of which samples from this part of the country were lacking in our collections.

A summary and discussion of the chronology in its present status may be set down here, always qualified by the unfinished nature of the work and by the scarcity of samples over the large areas covered. During the periods above called "pre-Old Empire" the Yucatán peninsula formed part of the range of a more or less homogeneous culture, extending over a large area which included the Petén. A major part of our Yaxuná pottery of this period was accepted by Mr. Smith as very similar to the Uaxactún pottery. The Yucatán collections contain pottery of this kind from almost every large site sampled. Certain pottery types in the Yucatán sequence which may tentatively be equated with early Tzakol show definite similarities to central Mexican pottery of the Early Ticoman period. The Yucatecan periods which equate with Tzakol and Tepeu I vary throughout the peninsula, having but a minority of their elements in common with each other and with the Petén. Petén polychrome trade wares occur in small percentages, and stand out sharply from the native wares. The period herein called Puuc follows the above and is characterized by the dominance of slateware, the antecedents of which appeared in the preceding periods. This period is quite uniform throughout Yucatán, as are the following periods up to the conquest.

An interesting side light on pre-Old Empire architecture is furnished by the contents of three trenches dug in the lower slopes of a large pyramid (15–20 m high) at Yaxuná. The trenches were so dug as to pass through only post-constructional refuse and post-occupational slump. The pottery, beyond a few late

surface sherds, is exclusively and typically of the pre-Old Empire period. Yaxuná, with its evidences of long and early occupation and its suggestion of influence on Chichén Itzá (Morley 1938:546–547), should certainly repay excavation.

Our large collections from the Puuc region sites of Labná, Sayil, and Kabah contain no pottery equivalent to that of the Mexican period at Chichén Itzá. Uxmal contains only a small fraction of one percent. Thus these sites must have been abandoned before, or at the time when, the so-called Mexican period reached Chichén Itzá. North of the Puuc hill range near Ticul, however, as well as north of Mérida, and at Mayapán and Chichén Itzá, widely separated sites, the Mexican period is represented. The rise and major occupation of Mayapán coincided with the decline of Chichén Itzá. This fact is proved beyond reasonable doubt by stratified deposits at the two sites.

The collections on which we have worked until now contain no deposits dating from the transition between the Maya and the colonial periods. The color and finish of the earliest colonial slipped ware in our collection and that of the Mayapán pottery are very similar, but there are various changes in forms between the two periods. The small collections we have seen from Tulúm definitely belong to the Mayapán period. Tulúm was probably occupied at the time when the first Spaniards saw it (Lothrop 1924). Tradition places termination of the occupation of Mayapán at about 100 years before the conquest (Landa 1941), and the ceramic evidence certainly does not refute such a dating.

As can be seen from the above data, the purpose of this season's work is on the way to accomplishment. We have every reason to believe that, by the end of year a ceramic sequence equating with Petén ceramic sequence and extending to the colonial period in Yucatán will be available from the material already excavated. In addition, a re-examination of the long-held theory that the major cultural development of Yucatán coincided with the decline of the Old Empire has been made advisable by the increasing evidence that Yucatán supported a considerable, widespread, and culturally advanced population during and before the time of the Maya Old Empire, and that this population in most cases used the same architectural centers, even the same pyramids, as did the people of the heretofore emphasized New Empire. There is no evidence of a major break in Yucatecan pottery tradition between the times of the Old and New Empires and certainly no evidence of a sudden influx of Petén Old Empire influence during this period, when a migration, either cultural or physical, into Yucatán has been thought to have occurred.

The pottery collected this season has added several new wares, and extensive data on form and decoration,

to the known Maya ceramic repertory. Perhaps more important have been the stratigraphic data which have permitted the chronological placing of many kinds of pottery previously known only from isolated sherd samples and whole pieces. Data on the variation between samples of the same ware gathered from various localities have added to our knowledge of cultural distribution and exchange. The continuance of the policy of placing the architecture in the ceramic chronology by its accompanying pottery has been made possible in several instances this season through the work of Mr. Andrews on three of the sites included in this report.

This study should represent but the beginning of more intensive and illuminating work. It has not been conducted as an end in itself, but as a tool to aid in the unraveling of the broader aspects of prehistory in the Yucatán peninsula. The necessarily involved and time-consuming work now nearing completion should permit the approximate dating, or at least the placing in an anchored chronological sequence, of any ruin, standing or fallen, in the area. Only two of the six Yucatecan pre-conquest periods tentatively outlined in this report are at all well known, the Puuc and the Mexican. Architectural work on the immediately preceding and following periods has recently been begun by Messrs. Pollock, Shook, and Andrews.

The present ceramic sequence is merely a dating outline. The order of the periods described has been stratigraphically proved, but much could be gained by further study of developmental changes between the periods, cultural interconnections, regional variations, and craft techniques. Further ceramic studies should go hand in hand with the archaeological excavation necessary to furnish a complete picture of the several horizons, the chronological placing of which has been indicated by this survey.

4.11.

ANNA O. SHEPARD

Ceramic Technology

YB 41:271-272, 1942

The study of Plumbate Ware has been the principal project of the year. This ware, important because of its wide distribution in Middle America and its con-

sequent value for correlating occupations and establishing contacts, has for nearly 60 years been an archaeological enigma. The place of its manufacture is unknown, and postulates regarding that center have included such distant regions as Salvador and south-western Chiapas. From the standpoint of ceramic technique it is the most highly developed Middle American ware known, yet its peculiarities have been completely misunderstood and erroneous speculations have gained acceptance through frequent repetition. Technological analysis is therefore required. The ware also affords opportunity for a somewhat different approach from that which has been made in previous technological studies of Middle American pottery. In earlier work, pottery recovered from a single site has been analyzed for the purpose of defining occurrences. A considerable amount of time has therefore necessarily been devoted to the study of local wares of inferior quality which had no trade value and which consequently do not directly contribute to investigations of the interrelations of peoples. In the Plumbate project, on the other hand, attention is concentrated on a highly specialized and widely traded ware. All its geographic occurrences and ceramic associations are being studied. We are considering the indications which paste gives of the place of its manufacture, the degree of variation in the materials used and the possibility of admixture of clays, the relative importance of firing method and properties of the clay in their effect on the quality of the surface, the frequency and method of imitation, the possibility of trade in raw materials, and the comparison of contemporaneous wares in composition and workmanship.

In this study it has proved advantageous to observe technological and stylistic traits simultaneously. The technological work has included analysis of the surface material, thermal experiments to learn what methods of firing were employed, and petrographic analysis of the paste. In the study of surface material, spectrographic analyses have been made of 15 samples, together with comparative analyses of 25 samples of common red slips. We have been fortunate in having the privilege of using the 35 foot [10.7 m] grating spectrograph of the Massachusetts Institute of Technology. X-ray analyses of several samples have also been made by courtesy of Drs. Grim and Bradley of the State Geological Survey of Illinois. These results, together with those obtained by microchemical, determination of the three major constituents, definitely correct the idea that the vitreous appearance of the ware results from a lead glaze. The analyses also explain in large measure the distinctive surface qualities of this most unusual pottery. Except for the single analysis by Loeb in 1903, made before the development of refined methods of handling small samples, these are the only analyses ever made of the glaze material.

A series of firing experiments has been conducted to learn what temperatures and firing atmospheres would produce the peculiar hard, gray surface of the ware. Soft, red, under-fired portions of Plumbate sherds have been changed to the typical hard, vitreous surface in these experiments.

Because of the extremely fine texture of the paste, petrographic analysis has been more exacting and time-consuming than has that of other wares. The 150 sections studied are from several sites in the western Guatemalan highlands, and from Alta Verapaz, Salvador, and Chichén Itzá. Various sherds thought to be either of mixed material, or imitations have also been analyzed. The paste is distinctive in composition and unquestionably offers, the best clue to place of manufacture of the ware. In spite of the great importance of Plumbate, its stylistic features have never been fully described, partly because published studies have, in general, been based on small collections. In order to correlate stylistic and technological features and to compare them with those of contemporaneous wares, it has been necessary to obtain from many sources the available data on style. This stylistic material will be included in the final report on Plumbate. A record has been made and photographs have been obtained of the Plumbate vessels in the principal museums of the United States. Over 250 vessels are now represented in the file; the record includes profile drawings, and detailed measurements from which basic proportions have been calculated, and data on surface qualities and workmanship. To facilitate the analysis of style, drawings have been made by Miss Janice Snow of incised designs, and such details of effigies as features and objects of adornment. The mass of stylistic data which has already been collected, when extended by field studies in Central America, will, it is hoped, serve to corroborate and strengthen the results of technological analysis.

Guatemala and Salvador were examined, and with the assistance of Miss Janice Snow in tabulating and sketching, a complete descriptive and photographic record was made of Plumbate vessels in the national museums of the countries visited and in 10 large private collections. The most generous cooperation was received from museum officials and owners of collections. The file on Plumbate Ware has thus been extended by 344 vessels and now furnishes an adequate basis for defining Plumbate style and workmanship, a task necessary in order to determine the relationships of this important ware.

While in Guatemala, Miss Shepard visited the site of Tajumulco in company with Mr. Shook, and short reconnaissance trips were made to several nearby sites. The frequency of occurrence of Plumbate in this area, as well as indications of the population which the region supported, are of particular interest because of the large collection of Plumbate vessels excavated from Tajumulco under the auspices of the Museum of New Mexico.

Several weeks in Guatemala City were spent in microscopic examination of sherds from the 1942 excavations of Mr. Thompson at El Baúl and Mr. Shook at Kaminaljuyú. Subsequently Plumbate Ware from both sites and other wares from El Baúl, particularly that called Tiquisate, which is associated with Plumbate and bears some resemblance to it in oxidized surface colors, were thin-sectioned in the laboratory and analyzed petrographically. When the paste and slip of Plumbate from El Baúl and Kaminaljuyú were compared with those of typical Plumbate, Miss Shepard noted minor differences, which may be significant in view of the distinct vessel shapes characteristic of these two sites.

The remainder of the year has been devoted to the preparation of the Plumbate report.

Ceramic Technology
YB 43:173–174, 1944

The interruption of archaeological field work has reduced the volume of routine analysis of paste required of the technological laboratory, and thus afforded time for the study of aspects of ceramics ordinarily consid-

ered outside the technological field. The desirability of fully correlating stylistic and technological data and of using technological analysis to aid in the solution of well defined archaeological problems has often been stressed but seldom found easy of accomplishment. One way of facilitating such correlations is for the technologist occasionally to undertake general ceramic investigations. The study of Plumbate Ware, described in the last annual report, led naturally to two broader studies, one of design symmetry, the other of pottery form; these have constituted the principal projects of the year.

The design study was initiated by an attempt to compare the symmetry of Plumbate design with that of Fine Orange Ware, which had been described by Dr. G. W. Brainerd. A series of experiments with symmetry showed that the usual concepts and accepted definitions are limited to those relating to finite designs; it is not ordinarily realized that infinite linear or one-dimensional designs involve higher types of symmetry and are of seven basic classes, instead of three as in the case of finite designs. A method of classification was therefore developed for linear or band designs, and its applicability, as well as the significance of the evidence obtained, was tested by analyzing a large series of designs from four Southwestern and three Middle American wares which are well illustrated in the literature. The Southwestern design systems chosen for study were: that of Mesa Verde, representing rectilinear and cursive design of the Classic Pueblo period; that of Pecos Glaze Paint Ware, for simple panel treatment in a medium which required progressive design Simplification; that of Santa Domingo, for curvilinear design of the historic period; and that of Classic Mimbres, chosen because of the complexity of its structure. The Middle American systems included, in addition to Plumbate and Fine Orange, that of Coclé, Panama, pottery, which is characterized by specialization in scroll patterns. The contribution which symmetry makes toward the understanding of design relationships was compared with that of structure and design elements which are recognized criteria in design analysis. Results of the study have been summarized in an illustrated paper.

Form is of primary interest to the student of Mesoamerican pottery because of its diversity, and particularly because many forms appear to be peculiar to periods or regions. It seemed desirable at this stage to summarize our knowledge of pottery shape in order better to trace the distribution of specialized forms and to understand the influence of one region upon another as revealed by the sum total of form traits. A card index of pottery form has therefore been started to facilitate such a summary, and also to guide the systematization of form classification and definition, and

to lead to broad comparative studies of the pottery shapes of different culture areas. To date, over 1,000 cards have been prepared, and a consistent working classification has been devised. The task of checking reports for this material has incidentally constituted a suggestive review of ceramic literature.

In the fall, six weeks were spent in the East were devoted in part to library work in the Peabody Museum at Cambridge, and, in part to the study of museum collections. Details of costume shown in codices, sculpture, and pottery were reviewed for comparison with representations on Plumbate effigy vessels. The study of museum collections followed a series of experiments with incised decoration planned to ascertain whether or not the use of different tools such as the gouge, knife, and point could be recognized. The effects of paste hardness and texture on the quality of line work were also investigated, and an instrument for measuring the depth of incised lines was devised.

Petrographic analysis during the year was limited, first, to a revision of the technological notes for the Kaminaljuyú report, together with further study of volcanic ash temper with relation to the question of the extent to which ash from different sources can be recognized; and, second, to the analysis of stucco and pigment samples from fresco-decorated wares of Guatemala, Mexico, and Salvador. In the stucco samples, a variety of materials and techniques was recognized which should aid in identifying the work of particular schools of stucco decoration.

In anticipation of the preparation of a handbook on methods of pottery analysis, a bibliography has been prepared which covers current periodical literature on recent ceramic research, and analytical method of interest to the technologist. In the same connection, recent literature on color standards and color nomenclature has been reviewed.

4.14.

ANNA O. SHEPARD
Ceramic Technology

YB 45:211-214, 1946

The temporary cessation of archaeological field work during the war afforded opportunity for investigations which were departures from those previously con-

ducted under the Ceramic Technology Project. Two principal studies under this extended program, that of Plumbate, an important Mesoamerican ware, and that of symmetry in abstract design, were completed in the current year. The advantages of broadening the scope of the project are apparent in view of the extreme specialization, which archaeological ceramic technology represents. During the period of establishment of the project, the accumulation of material and the necessity of testing the applicability of many analytical methods restricted Miss Shepard's activities to the purely technical aspects of ceramic research. There was then a large backlog of pottery from earlier excavations, and collections continued to come in from season to season. Extensive analyses were required in order to ascertain the range of materials and techniques used by the Maya and to gauge their possible significance in comparative studies; also the archaeologists reporting on pottery needed data to aid in their classifications. By the end of 1942, systematic and detailed analyses had been made of the more important collections and preliminary study of the others had been completed, many thousands of sherds having been examined microscopically and a variety of techniques identified by chemical and thermal tests. Although only a small part of the data thus amassed has so far been published, they have been made available to five archaeologists working on pottery under the auspices of the Division.

The disadvantages of extreme specialization were frequently apparent during this initial period, especially in attempting to correlate technical and stylistic features. Consequently, when the war stopped the flow of material from excavations, it seemed advisable to choose an archaeologically important ware and study all its aspects, since in this way the leads suggested by relations of composition and style could be followed by means of additional tests and experiments. Plumbate Ware was selected for this purpose because its wide distribution through trade makes it particularly useful in relating occupations, and also because it presents interesting problems of origin and development. The study was a long-term one, having been initiated with the analysis of sherds submitted at intervals by various archaeologists, and later extended by the examination of large museum and private collections. Reports on the work have appeared in previous *Year Books* [Chapters 4.4, 4.5, 4.8, 4.9, 4.11–4.13]. One recent result brought out in the final revision of the manuscript may be mentioned as typical of the usefulness of mutually supporting data on composition and style. The variety of Plumbate represented by sherds from Kaminaljuyú and El Baúl is distinguished not only by vessel shape, but also by a consistent difference in paste. Archaeological evidence indicates that this va-

riety antedates the better-known and widely traded variety. With two independent criteria for identification, the significance of hitherto puzzling specimens from Tajumulco in the far western highlands, as well as that of certain outstanding specimens from older collections, could be postulated with confidence. These data give a new frame of reference for the long-standing question of the place of origin of the ware.

The stylistic work on Plumbate led to a general review of pottery form and of certain aspects of design. In the search for fundamental properties of abstract design, symmetry was chosen for more intensive study. To the mineralogist, it affords a natural approach because the principles used to describe the form of a crystal are equally applicable in defining the arrangement of regularly repeated parts in a motif, a band, or an all-over pattern. Although several mathematicians have illustrated this fact, their method has been overlooked by students of art, and the concept of symmetry found in the literature of aesthetics is too limited to be of value in design analysis. In general this literature, including that in the field of philosophy and psychology as well as in that of pure and applied art, is dominated by the attempt to evaluate, a process which is irrelevant to the anthropological approach. The archaeologist may study design either as a criterion for identifying pottery types and as a means of following contacts of peoples through the spread of art styles, or as a cultural trait, in which instance he will consider such questions as what characteristics are common to the decorative art of all people, what features are most subject to change, how a style develops, in what ways artistic standards vary from time to time, and how new elements are assimilated. In either case, his individual tastes and those of his time have no bearing on his investigation, and his first problem is to recognize fundamental properties and to define them unequivocally. For the most part, archaeologists have previously centered attention on elements, motifs, or symbols and on methods of composition. These are particular features, treated descriptively. In contrast, symmetry permits classification by general, basic categories. The six different pottery styles which were used to test the significance of symmetry in design history exhibited a marked degree of variability in this property and at the same time showed its direct relation to design structure. The effect of symmetry on the less well defined characteristics of balance, rhythm, and dynamic quality was demonstrated by experimental constructions. Thus it has become apparent that symmetry is one of the fundamental features of formal design and that it lends itself particularly well to exact classification.

The effective utilization of the facilities of the Ceramic Technology Project is largely a problem in integration of evidence. We have in the Maya field particular

advantages for ceramic studies, and also some handicaps. These can be weighed by comparing conditionally those in the Southwest, where the value of the method was first tested. Maya ceramics offers a richer field for research: first because there is variety and refinement of decorative techniques reflecting the cultural advancement of the people, and second because there was much more extensive trade than in the Southwest, and it is in separating imported from local wares that petrographic methods have proved particularly useful. Our principal unfavorable factor is the difficulty of sampling pottery. Because of the rarity and weathered condition of surface sherds, it has been impossible to plot distribution of types by the economical method of surface survey which has been so fruitful in the Southwest. Also excavations have in many instances been in the nature of tests in widely separated regions from which it is difficult to make a well rounded historical reconstruction. For example, we may establish a sequence from a carefully excavated site, but as long as our knowledge of the ceramics of the surrounding area is blank, there is insufficient basis for distinguishing local from imported wares. Nor can we judge whether changes reflect indigenous developments or result from the introduction of new ideas or from replacement of populations. These circumstances have tended to reduce the work of the project to routine identifications for purposes of classification and record, thus supplying a necessary foundation for future investigations at the risk of wasting effort on details which may prove eventually to have no general archaeological significance.

A second circumstance seemingly unfavorable to technological work in the Maya area is the wide distribution of two commonly used tempering materials, limestone in the Petén lowlands and the Yucatán peninsula, and volcanic ash in the highlands. Small unrelated collections have probably exaggerated the handicap of this condition, as is shown by the fact that recent analyses of a well selected sample of Miraflores pottery showed a number of distinct varieties of ash, each associated with particular stylistic types. The possibilities of identifying material from different sources are therefore much better than they at first appeared; consequently our principal problem is one of sampling.

The studies of the past few years have demonstrated the advantages of extending the scope of the project and have suggested means of avoiding the limitations imposed by detached collections. Intensive study of archaeologically important wares or types best reveals trade relations and the spread of ceramic traits, and also most effectively illustrates aesthetic standards. In such studies we are not dependent on small sherd lots from single excavations, but can bring

together evidence from collections of the entire area. Usulután, a well distributed ware of the early horizon, has been chosen to trace the spread of a decorative technique and to locate centers of manufacture and the extent of their trade. There are also groups of types which would repay more detailed review in this way; for example, certain polychromes of the Petén and the Fine Orange types of the Gulf Coast. A second method of approach is by cultural regions, summarizing, comparing, and interpreting all available data. This would give a clearer picture of the similarities and differences of regions and show which among a complex of traits had the widest influence and which were specialized and restricted. It would also enable us to weigh the influence of environmental factors, the effect of natural resources on ceramic development. Both types of investigation would require close correlation of technical and stylistic evidence and would have as their primary aim the understanding of trends of development and the interactions of cultures as reflected by pottery. Finally it is our responsibility to make available to the archaeologist that part of our experience in ceramic analysis which would be useful to him. An archaeological ceramics handbook is therefore being planned.

4.15.

ANNA O. SHEPARD
Ceramic Technology

YB 46:190-192, 1947

The principal activities during the current year have been preparation of material for a ceramics handbook, study of a punch-card system, and preliminary analysis of Usulután ware. In addition, a section was added to a paper on the symmetry of abstract design, previously considered completed. Early material from the Pueblo region recently published by Dr. J. O. Brew suggested the new section, which is devoted to all-over patterns and a review of evidence of the influence of basketry design on early pottery design.

The purpose of the ceramics handbook is threefold: 1. To present for the archaeologist that part of technical and scientific ceramics which is applicable in our field, 2. To summarize and critically to evaluate methods of archaeological ceramic description and analysis, and 3. To consider the place of ceramic data

in archaeology and to examine the basis of our interpretations. There has long been need for an outline of ceramics written expressly to give the archaeologist background for understanding the technical features of pottery, particularly as scientific knowledge of the clay minerals has undergone marked advance in the past 20 years and much pertinent information has appeared only in technical journals. The review of analytical procedures will cover shape and decoration as well as technical features. A number of methods developed in our own work will be described, and attention will be given to field tests for the archaeologist.

Our ceramic studies have reached the stage at which a comprehensive review has become desirable. Extensive summarizations and comparisons require means of sorting rapidly the accumulated data. The practicability of a punch-card system for hand sorting has been tested in both technical and stylistic work. Immediate application of the system in technological analysis was found in an index of our collection of some 3,500 thin sections. A code covering provenience, period, pottery classification, paste composition, and various technical features has been devised, and cards have been printed. Sections of Petén and Copán pottery have been indexed to date, and the advantages of the method have been effectively demonstrated. Punch cards have proved no less applicable in stylistic analyses, particularly of entire and restorable vessels. Revision of method in these studies is desirable because our material is limited in extent and is scattered. To base comparative and distributional reviews on published illustrations is time-consuming and often unsatisfactory. Doubtless the fact that the bulk of archaeological ceramic material is in the form of sherds has directed and restricted our studies more than we ordinarily realize. We have inevitably been led to give undue prominence to secondary features such as color, texture, and wall thickness because they are easily determined in the fragment, which may give only a hint of vessel shape and design. Consequently ceramics as an aspect of material and artistic culture has been neglected for potsherds used as a tag for place and period. Without depreciating the potsherd, one may point to the desirability of bringing together a record of available, significant, entire vessels. A photographic file such as that started in the Cambridge office of the Division of Historical Research is beginning to be recognized as a requisite for comparative work; but with the ordinary indexing system it soon becomes unwieldy, and locating specimens and returning them to the file is discouragingly time-consuming. Punch cards fully meet this difficulty, since with a sound and comprehensive code a wide variety of classes and of specific traits can be sorted rapidly; moreover, filing is eliminated. Considerable time has therefore been given to

the development of systematic classifications of vessel shapes, decorative techniques, and design styles to insure a logically consistent and comprehensive code. A trial set of cards prepared for Usulután Ware is being used to test the code. It is hoped that when the system is perfected, other institutions will be sufficiently interested to adopt it and thus initiate a co-operative project for exchange of material. A number of archaeologists, including a large group of Mexican authorities, have been consulted on the code for cultural regions and have shown a splendid spirit of cooperation.

Usulután, the principal type of pottery analyzed during the current year, is one of the more widely distributed wares of the Archaic period and therefore affords opportunity for study of contacts and spread of influence on that horizon. Neither the decoration, which is simple and geometric in a technique long misunderstood, nor vessel form, which is varied and elaborate, has so far shed light on centers of production or on volume and extent of trade. The ware occurs mainly in the region of younger volcanic formations of Guatemala and Salvador; most of it is tempered with volcanic ash. When these conditions obtain, the feasibility of using paste composition to distinguish pottery from different sources may be questioned, and the Usulután study can therefore be considered a test case. The preliminary microscopic examination of a large collection from Miraflores and smaller samples from Copán, a number of localities in Guatemala, and several in Salvador has been encouraging. Eight distinct varieties of ash associated with different types of clay have so far been noted. Their distribution indicates distinct sources, and it is clear even from the preliminary examination that the ware was made in a number of districts and that there was considerable interchange between them. Relations will be plotted in detail as analysis proceeds. Possible local variation in style will also be studied by correlating form and composition. This evidence bears on the question of broad trends in ceramic history. It has appeared that the pottery of the Archaic period exhibits less regional specialization than that of the Classic, a possible difference which suggests a general parallelism with Pueblo ceramic development. But individual styles are less conspicuous among the predominant monochromes of the Archaic than among the polychromes of the Classic, and the fundamental obstacle in testing this generalization has been uncertainty as to amount of exchange and inability to distinguish indigenous from imported pottery by appearance alone, except in the case of a few striking types. There is now assurance that composition will afford a reliable basis for investigating the problem of local specialization in this area as it has in others.

4.16.

RAYMOND H. THOMPSON

Ceramic Studies

YB 49:202, 1950

Ceramic studies in connection with the Division's new program of research in the archaeology of the historic and protohistoric periods in northern Yucatán are being carried on by Raymond H. Thompson under an Institution fellowship. Thompson, a graduate student at Harvard University, will use the results of his studies for a doctoral dissertation. Special attention will be focused on pottery from early colonial and conquest period sites in an effort to define not only the time relations involved, but also the developmental interchange, and persistence of local cultural trends as reflected in ceramic traditions. Work was begun in February 1950 on the task of organizing the material already published and analyzing the available museum collections. Lengthy visits with Dr. George W. Brainerd of the University of California at Los Angeles, and Dr. Anna O. Shepard were planned in order to familiarize Thompson with the results of recent work in the area and with basic technological methods for use in the field analysis of pottery fragments.

The bibliographic work was temporarily abandoned and the conferences with Brainerd and Shepard were postponed until the summer in favor of a study of the ethnographic data on pottery shapes and functions to be found in the codices, wall paintings, and other forms of artistic representation. This project was suggested by Dr. Shepard, who hoped that some definition of function according to shape would result from it. Three months were spent in carefully searching the literature for representations of vessels, mainly from the three Maya codices, wall paintings, sculptured stone, and painted pottery. An ink tracing was made of each example found. Only the container itself was thus copied. Data on the position of the vessel, the person holding it, the contents, and the associated objects were included in a series of notes organized under the following categories: bibliographic reference, provenience, color, association, contents, quotation from the literature, and comment on function. The tracing and notes for each representation were recorded on cards which were filed according to a broad shape classification.

The results of a preliminary analysis of the over 400 examples are disappointing in terms of a functional study. Several factors contribute to this. Most of the source material is concerned with the representation of ritual events, which gives a ceremonial bias to

any functional conclusions. The small number of wall paintings and codices available narrows the range of shapes and uses. Moreover, the styles of representation and the different media used produce too high an individual variability in the representations of a single shape to justify a very detailed shape analysis. Because these factors so hamper a functional study, the emphasis has been shifted to a more purely ethnographic approach. A composite "type" of each of the shape classes will be compared with pottery vessels excavated from archaeological horizons. Thompson plans to write a short paper based on this comparative study of archaeological vessels and the representations of them found in Maya art.

4.17.

RAYMOND H. THOMPSON

Yucatán

YB 50: 232-236, 1951

One of the most rewarding aspects of the Institution's Fellowship program is the ever-present opportunity for the Fellow to gain experience and professional training from association with older members of the staff. Several such opportunities made in the period under review particularly productive in this respect. Early in the year, between five and six weeks were spent with George W. Brainerd, who provided both a basic knowledge of Yucatecan ceramics from the material he is preparing for publication, and a review of the statistical methods which have been developed for analyzing these data. A similar period was devoted to studies in ceramic technology with Anna O. Shepard. These studies consisted of an explanation of the methods used to analyze pastes, instruction in the microscopic identification of tempers, and an examination of the characteristics of the known Yucatecan pastes. After the season in Yucatán had begun, several members of the staff devoted themselves to the task of cleaning, sorting, classifying, and storing the huge ceramic collections which were in Mérida. This co-operative effort converted an otherwise monotonous and time-consuming job into an informal ceramic round table.

The research project of the past season consisted in an examination of Yucatecan ceramic materials in terms of Gordon R. Willey's "pottery tradition" concept, with special emphasis on the late prehistoric,

colonial, and contemporary periods. Although the problem in its purest sense is concerned with all those traits which run counter to horizontal changes and persist throughout parts or all of the pottery sequence, very little work has been done on early sherd collections. Study of the lower time horizons has been limited largely to the brief analysis made possible during the arrangement of the collections in Mérida. The major effort was concentrated on obtaining sherd samples from the little known late pre- and early post-conquest period. In spite of the importance of this time period to the Department's program, its ceramic components are only scantily represented by collections from Dzibilchaltún, Telchaquillo, and Maní. An intensive search this season for additional sherd deposits of this date has met with negative results.

During recent years Roys has been compiling a list of sites which show promise of yielding this type of ceramic evidence. In *Year Book* 48 [Chapter 9.28], he suggests the towns of Candel and Uxú as sites worth investigating. In order to appraise the digging possibilities of colonial sites still occupied, these two towns and a third, Chuburna de Hidalgo, were visited early in the season. Located north and west of Mérida, they were founded very soon after the conquest. All three have prehistoric ruins near the plaza and church. In each case, however, the long and continuous occupation of the same small plaza area makes it very unlikely that excavations would produce samples of conquest-period sherds, and the chances for a pure, unmixed deposit are even smaller. Certain features of the prehistoric remains are worth noting. Chuburna has three very small mounds, perhaps what is left of larger mounds, to the north and west of the church. These are being gradually destroyed to provide fill for leveling the plaza in front of the church. They appear to be dry rubble. No sherds were found despite a careful search.

Shook and Thompson made a second visit to Candel and Uxú to survey the ruins there. North of the church at Candel are the remains of six mounds, one of which was recently quarried away for the construction of the Mérida-Hunucma highway. Several floor levels appear where streets cut the edges of mounds, and there are masonry exposures on the two largest mounds. The approximately 8 m. high substructure of Mound 1 is by far the largest unit on the site. The masonry of two successive terrace constructions is exposed on the northwest corner. There is also a stairway on the south side. The masonry is of medium-sized blocks of roughly shaped but undressed stone which suggest Early Classic.

Mound 2 contains a circular wall about a meter thick and a little more than 5 m in diameter. This "round" structure is made of stone blocks of the same type as the stairway and terrace walls of Mound 1, but

the courses are liberally chinked with small stone fragments. Sherds collected from the fill thrown out during recent quarrying activities include some thin slate ware pieces which would reinforce the suggested dating for the Mound 1 masonry, perhaps raising it to Middle Classic. Round structures are not characteristic of this period; yet the masonry does not conform to the style known for the Postclassic period, when round structures do appear, nor was there noted anywhere at the site well cut and dressed stone such as is characteristic of Late, and Postclassic periods in Yucatán. This leads Shook to believe that "the masonry style suggests that the round temple, pyramid, and other structures at Candel belong to a period earlier than Late Classic." Shook also thinks that the round structure had a single doorway opening to the east. Thompson, on the other hand, is inclined to believe that this circular wall does not represent a "round" structure contemporary with the probably Middle Classic site, but rather the remains of a rainwater cistern built by the early Spanish settlers of Candel with stones robbed from Mound 1 or from a mound with similar masonry now destroyed. There are cisterns in a fair state of preservation among the ruins of the abandoned colonial towns of Hunacti, Calotmul, and Tecoh which have similar masonry and the same range of wall thickness and diameter. The fact that these cisterns are usually built into the side of a prehistoric mound would account for the association of thin slate sherds with Candel structure.

There is only one mound at Uxú, close on the north side of the church atrium. As a substructure about 8 m high with remains of a floor on top and a few veneer-style stones scattered about the sides and base. In the plaza Shook found a jamb stone, cut to full wall width, and part of a sculptured round column. The latter was broken just above the knees of the male figure which is carved on one side in low relief. The lower legs and the end of the breechcloth are all that remain. The sandals on the out-turned feet have a round ornament over the toes. The best guess for dating Uxú is Late Classic, somewhat later than Candel.

Roys [Chapter 9.28] also lists seven abandoned sixteenth century villages as likely to yield undisturbed deposits of the conquest period. These are Calotmul south of Tzucacab, Cauich just outside Oxkutzcab, Hunacti north of Tixmeuc, Kanchunup near Sotutá, Kizil near Uman, Tecoh east of Izamal, and Tuchicaan near Maxcanú. Three proved to be unsuitable for ceramic studies. The colonial town is completely destroyed at Tuchicaan, and all that remains at Cauich is a trace of some of the walls of the visita church. Although the Kanchunup church and atrium are well preserved, there is so little soil in the vicinity as to make it almost impossible to dig.

It was decided to select from the other four sites the two which, coupled with the colonial material that Brainerd obtained at Maní, Telchaquillo, and Dzibilchaltún, would give the best distributional sampling of the region. Kizil is still a very promising site, but, like Dzibilchaltún is in the Mérida area. Calotmul and Hunacti are quite near together in southern Yucatán. Since Hunacti was abandoned earlier, and therefore is more likely to yield a pure sample, it was selected for excavation. Calotmul, with its somewhat longer period of occupation, may yet prove to be the most favorable place to dig. Tecoh was chosen as the other site to be tested because its location in the north-east would considerably extend the areal coverage of the project.

There are fairly extensive prehistoric ruins at both Hunacti and Tecoh, those at the former being considerably larger. Although pottery of Preclassic and Classic types is common in both samples, no sherds have yet been identified as surely dating from the time of the conquest. Both sites have well preserved visita churches and associated colonial buildings which provide considerable information on the arrangement of an early Yucatecan colonial village.

It is difficult to explain why no conquest period sherds appeared in the excavations. The most plausible explanation places the blame on the time-honored custom of burning the milpas. The short occupation of these sites did not allow time for large accumulations of colonial pottery, and what did accumulate was on or near the surface. All known pottery of the period was tempered with calcite, a type of temper which does not stand up under intense heat. Consequently, unless in well protected and as yet undiscovered places, the thin soil cover characteristic of Yucatán has not provided enough insulation against the heat of the periodic milpa fires. This same argument can be invoked to account for some of the difficulties encountered in obtaining adequate surface sherd collections from most Yucatecan sites. One can walk through many a milpa near a ruin and pick up sherds in a well advanced state of deterioration induced by the fires of the burning milpas and aggravated by the heavy rains of the summer months.

At Roys' suggestion Thompson searched for and located two other colonial sites. It was hoped that some early Spanish sherds might be found at Tzucuaixim, which in 1605 was a sugar finca near Mérida. With the help of D. Juan Martínez Hernández, the present Quinta San Pedro Tzucuaixim on the eastern outskirts of Mérida, in the Chuminopolis section, was found to occupy the site of, and to preserve the name of, the old finca. The disturbance caused by lengthy and recent occupation makes this an unlikely place to dig. The other site, Yacman, was identified by Roys through

documentary evidence as a sixteenth century village with a visita church. At Hacienda Mahzucil, an annex of Hacienda Xcanchakan, the name *Yacman* is still used by the local people for a good-sized cenote about 2 km southeast of the hacienda center. There are a few small mounds near the cenote, and not far away the badly ruined remains of a rather small visita church. A surface collection of weathered potsherds included no fragments which could safely be dated later than the Classic period.

As noted by Shook [Chapter 4.17], he and Thompson made a collection of sherds from the ruins of the old convent of San Francisco in Mérida. Most of the sherds recovered are bolster-rim slate ware basins typical of the Late Classic. Through the courtesy of Dr. Eduardo A. Duarte E., Thompson was able to visit a newly discovered cave about 2 km southwest of Tekax. Sherds and two large jars found in the cave were Classic-style slate wares. Several large jars were found almost buried in calcareous deposits, pointing up the ancient practice of setting vessels in the caves to collect water from slowly dripping sources.

The failure of the concerted efforts during most of the season to obtain samples of conquest-period pottery has led to a stronger emphasis on the study of the archaeological and technological significance of present-day pottery making in Yucatán and Campeche. This type of investigation is aimed at tracing the "pottery tradition" through traits which seem to persist from prehistoric times into the contemporary period. Throughout the season considerable miscellaneous information on this subject has been collected, and as this report is being written, a systematic study of the main pottery-making centers of the region is being undertaken.

4.18.

ANNA O. SHEPARD
Ceramic Technology

YB 50: 241–244, 1951

During the past year stocktaking with respect to Yucatán ceramics has been carried on concurrently with the preparation of the book *Ceramics for the Archaeologist*. Experimental work with ceramic standards and methods of pottery making has extended the lat-

ter task. One of the major trends in ceramic studies of recent years has been toward standardization in recording outward appearances and away from consideration of the potter's methods. Description of appearances has satisfied the demand for objective reporting and eliminated speculation regarding techniques. Yet the potter's methods are of greater interest in the study of cultural development than are physical properties which exhibit secondary variations caused by differences either in composition or in methods or in both. Laboratory analysis, by establishing the composition of materials and revealing evidence of the method of firing, obviates the need for mechanical handling of physical properties. Furthermore, definitive marks of various shaping and finishing processes can be recognized through experimental studies. In line with this objective of understanding something of the potter's methods, an extensive study has been made of surface texture and finishing techniques. Some time has also been given to the preparation of material to illustrate graphically certain basic principles of ceramics.

The principal collections of Yucatán sherds in this country were shipped to the laboratory in the summer and used during R. H. Thompson's five week period of training in the use of the binocular microscope for the identification of the major classes of paste. These collections comprise sherds from Chichén Itzá, Puuc sites, Cobá, Holactún, and Oxkintok, and from the major phases so far recognized, but they are selected sherds and include a disproportionate number of unusual and unidentified types. They are inadequate for a review of the pottery of any one period or site, but can be used for a preliminary study of certain technological aspects of Yucatán ceramics. It is especially desirable at the inception of the Yucatán work to summarize present knowledge as aid in formulating problems and judging methods of solution.

Specific questions that have guided the review are:

- Whether or not the pastes of Yucatán pottery are sufficiently varied to serve for identification of localized types and for the recognition of interregional trade,
- Whether or not trade pottery from outside the Yucatán peninsula can be recognized by paste alone,
- and c. How Yucatán pottery compares with that from known Petén sites.

Recognition of local specialization contributes to the understanding of stylistic relationships and development and is needed to avoid confusing regional with chronological variations when reliable stratigraphy is lacking. Yucatán collections examined microscopically in 1940 showed indications of regional variations that gave promise that paste would afford means of segregating regional intrusives from local products, a difficult or impossible task when data are restricted to surface features and types are mixed

through extensive interchange. Two lines of evidence are used in the technological approach to this question of local specialization and regional trade: first, plotting of geographic distribution of the various paste types, and, second, correlation of paste with form or other stylistic traits.

In view of the problem of regional specialization, the collections in this country have been used to identify and define the varieties of the main classes of temper in Yucatán, volcanic ash and calcite. The material studied to date has shown a number of distinctive varieties of calcite and limestone, but the volcanic ash appears comparatively uniform in structure and mineral inclusions. This uniformity suggests that the ash was obtained from the same or similar sources. The origin of the volcanic ash in Yucatán pottery was a mystery for a number of years, until Pollock found in the Mérida market pumice said to have come from the coast, where it is washed in by ocean currents. Recently, experimental pieces were made from a sample of this pumice. Although they did not show the same structure as the ash in the pottery, it is quite possible that the pumice has varied in different periods. Nevertheless, certain characteristics of the ash temper suggest a terrestrial source. In addition to splintery glass and stray fragments of pumice, the pottery contains particles of tuff, that is, fine-textured, consolidated ash. The tuff, which could not be derived from pumice, often has a reddish clay or a calcareous matrix, and appears too soft to have been water-borne. The source of Yucatán ash temper is therefore still a question. A reddish or orange argillaceous tuff has so far been found only in Yucatán pottery.

The uniformity and distinctiveness of Yucatán ash temper is a great advantage in the recognition of intrusive ash-tempered pottery. Sherds that have been classed as foreign to the Yucatán peninsula on the basis of technological analysis include a few identified types, many odd sherds which because of their rarity have been tentatively classed as intrusives by the archaeologist, and many small, weathered nondescript sherds which would ordinarily pass unnoticed. The vitric ashes of these sherds include the rare perlitic type, as well as fine vesicular pumice and volcanic dust readily distinguished from the ash of Yucatán paste. Also common is crystal ash, which has not been found in any Yucatán type, though it is present at Uaxactún. Another prominent class of foreign paste has the texture of untempered clay. It is found in certain gray wares as well as in the various types of Fine Orange. Some progress has been made in distinguishing varieties of this paste by the presence or absence of calcareous particles, volcanic dust, and foraminifera. Other foreign pastes are tempered with igneous rock, of which there are a number of kinds.

Although intrusive sherds are easily recognized by paste, their source is in most cases unknown, and we do not yet have enough data or materials from the regions with which there may have been trade to make comparisons. But in view of the fact that a considerable proportion of the intrusive sherds have no distinguishing stylistic features, it seems desirable, as collections become available, to make a technological survey of likely areas to establish the distribution of paste types. On the Gulf Coast, samples from Tres Zapotes have been studied, and Professor J. García Payón is supplying us with collections from sites in the central Veracruz area.

The sherds in the Yucatán collections that have been classed as of Uaxactún style by R. E. Smith have been examined microscopically to compare their pastes with those of the type collection from Uaxactún. Sherds identified as Tzakol are, with rare exceptions, calcite-tempered, whereas Uaxactún Tzakol is almost exclusively ash-tempered. There were undoubtedly many local paste varieties within the Petén which we have not sampled, though a number are certainly represented by intrusives in Uaxactún. The Tepeu-like sherds from Cobá include both ash and calcite varieties in the same styles. The ash is exceedingly uniform and differs in structure from Yucatán ash. It is noteworthy that the ash-tempered and calcite-tempered medial-molding bowls show minor variations in rim form and type of molding, a correlation which strengthens the inference that they are from different sources.

The most obvious difference between Petén and Yucatán pottery is in decoration. In contrast with the elaborate polychrome painted types of the Petén, the principal type of well finished Yucatán pottery, slate ware, is either unpainted or decorated with simple patterns in black. The ware is readily recognized and has long been known but has never been fully defined. Tests of the paint have shown that it is organic, which makes the ware unique among analyzed Mesoamerican wares. The blackish or dark brown paints of polychrome ware of the Petén are mineral (iron-manganese ores), and this appears to be the most common black paint of Mesoamerica. The only other example of carbon paint that has been sent to the laboratory is that on Classic resist-decorated sherds. Examples of this ware from Teotihuacán and from Copán and Quiriguá have been found to oxidize readily at 550 degrees C. The pottery was almost certainly fired above this temperature, and it is therefore probable that the ware was painted after firing with a vegetable extract and reheated just sufficiently to char it. Unlike this black, the paint of slate ware is oxidized with difficulty unless hydrofluoric acid is used to loosen the texture of the body. In this respect, Yucatán black is comparable to the carbon black paints of the Pueblo area. The pres-

ence of a fired organic paint indicates a highly adsorptive clay. Thermal tests have also shown that the clay of slate ware has an exceptionally low vitrification point. Beading and blistering are noted at 950° C. In some instances a clear glass is formed. Still another peculiarity of some examples of this ware is the fact that the light drab surface becomes dense black at low heat, indicating that it was treated with some organic substance after firing.

Because of the historical and cultural relations of the Petén and Yucatán, a comparison of ceramic technique in the two areas is of interest. The same classes of paste are found in both areas, the similarity being dictated partly by natural resources, as in the case of calcite temper, partly by custom, as in the case of sherd-temper, which appears in the early types of both areas. In contrast with the paste similarity, the difference in decoration is striking and raises the question whether or not the decline in ceramic art in Yucatán was influenced by limitations of natural resources. To answer this question fully would require an extensive survey of Yucatán ceramic resources. It is clear from our present knowledge, however, that Yucatán potters had unusual clays, and that even though they made no use of their low vitrification point, they experimented with them sufficiently to develop a unique ware.

4.19.

ANNA O. SHEPARD
Ceramic Technology

YB 51:263–266, 1952

Laboratory work on the technology of Yucatán pottery was supplemented by a trip to Yucatán during the latter part of April 1951. A week at the Telchaquillo headquarters of the Department enabled Shepard to make a microscopic examination of sizable samples of Mayapán and Puuc Period pottery recovered this season, to search for clay deposits in the cenotes and sascab pits of the site, to visit the pottery-making village of Mamá, and to attend the staff conference held at the end of the field season. The second week in Yucatán was devoted to the study of collections at the Mérida office. At this time Shepard also held conferences with R. E. Smith and Shook on the code which

will be adopted for the pottery punch-card file for the Mérida office, and spent a day at Maxcanú observing potters.

Not the least important advantage of the trip was the opportunity it afforded Shepard to work with R. E. Smith and Shook. The technological study of pottery is necessarily a co-operative project between the specialist and the field archaeologist who collects the material, knows its context, and formulates questions regarding it. The more the field archaeologist knows about technological methods, their requirements, possibilities, and limitations, the more effectively the facilities of the ceramic laboratory will be used. Familiarity with technological methods is best gained by observation of work in progress and actual participation in those phases of the work that do not require special laboratory techniques, one of the most important of which is preliminary paste classification with the binocular microscope. During Shepard's stay, Smith and Shook gained some familiarity with the characteristics of the different paste types and their range of variations, and a set of reference chips of typical and distinctive pastes was prepared for them.

Knowledge of the distribution and properties of clays and non-plastic materials of Yucatán is essential to a full understanding of the ceramic development of the region. The materials used by present-day potters afford a practicable and convenient introduction to this subject and their study has a direct bearing on questions of continuity of ceramic tradition. In September R. H. Thompson spent a week at the laboratory on his return from Yucatán and left his collection of potters materials for analysis. Since the geological formations of northern Yucatán are uniform, and the samples were collected from eight villages, from Valladolid on the east to Campeche on the west, these clays promised to give some indication of the types of material available to prehistoric potters. We were interested in the extent of variation in the properties of these clays, how they might affect the potters' techniques, whether or not montmorillonitic clays are common, since there is evidence that slate ware slip is of this type, and whether or not any clays now being used are comparable to that of slate slip.

The clays are residual from limestone. Some are calcareous, others noncalcareous, but all are very fine-textured and highly plastic. Their mineralogical composition was studied by means of differential thermal analysis, X-ray diffraction, petrographic examination, and staining tests. The preliminary results indicate that kaolinitic clays are more common than we anticipated, although at least one montmorillonitic type is represented in the series. Firing tests show that all except two of the clays are red-firing, and none of them retains carbon paint effectively. Since none is compa-

rable to slate slip, the latter is apparently not a common type of clay in Yucatán, and it may have been traded extensively in prehistoric times.

The tempering materials collected by Thompson are all calcites, but they differ in form, in degree of crystallinity, and in purity. A matter of interest is the percentage of temper used by potters and its adjustment to the requirements of the clay. Chemical determination of the calcium carbonate in the clays, in the tempered pastes, and in the insoluble residues of the tempers showed that the percentage of temper is uniformly high, but there is no evidence of adjustment of amount to compensate for either a calcareous clay or an argillaceous temper.

During the year, the detailed petrographic analysis of Yucatán paste was carried forward, together with the preparation of a punch-card index of thin sections to facilitate the study of distribution of types and correlations of paste and style. The four paste classes represented by Yucatán pottery (sherd, calcite, volcanic ash, and lumpy clay) are clearly distinguishable and easily identified; our principal task has been to determine whether or not there are varieties within them that are localized. A question of primary interest with regard to the ash temper is whether or not more than one source of supply is indicated. All thin sections of this paste have been reviewed in some detail with this question in mind. The ash in all these sections is comparable in form and in sparseness and fineness of mineral inclusions. The paste is distinguished by the occurrence of particles of tuff or indurated ash. The similarity of these examples suggests derivation of the ash from a single source or from similar formations.

As yet we have no clue to the occurrence of this type of ash in Yucatán. If sherd collections were available, the geographic differences in frequency of occurrence might narrow the likely area of its origin. The reference collections selected from pottery provided by previous explorations in Yucatán, and now stored in Mérida, were examined with this question in mind, but they proved to be too reduced to give statistical results. As a tempering material volcanic ash is far superior to calcite, which, aside from the grave disadvantage of limiting firing temperature in consequence of calcination and hydration, gives a granular texture unless it is very fine. One of the puzzling questions of Yucatán ceramic history is why volcanic ash temper fell into disuse. Possibly the source of supply was cut off, or pottery-making in the centers using ash was interrupted by political disorders and the custom was lost. Our first problem is to establish the time of its disappearance.

Calcite, everywhere available in Yucatán, is the one tempering material that has been used continuously up to the present time, and it shows a great variety

of types. Present-day potters are using two and sometimes three types, either mixed or for different classes of vessels. R. H. Thompson reports that the potters think certain types are superior for cook pots, an idea to which thermal tests have given no support. There is no reason to suppose that conditions were simpler in prehistoric times, but the homogeneity and distinctiveness of certain calcite-tempered pastes and their association with particular pottery types, or their limitation to certain regions and periods, leave no doubt that there was consistent selection. Only by systematic study of large and well distributed collections can the significant variations be recognized. To date a number have been defined.

The pastes of all sherds recognized as intrusive in Yucatán are distinct from the indigenous pastes. Also, a number of foreign pastes have been found among nondescript sherds. We are handicapped in establishing the source of these intrusives because of inadequate data on the pottery of regions with which Yucatán may have maintained trade. We are therefore attempting gradually to build up knowledge of distribution as collections become available for study. Four such collections were examined during the year: Dr. Wells Jakeman gave us the privilege of examining and preparing thin sections of his material from Aguatal near Laguna de Terminos; Dr. Gordon Ekholm gave us a series of representative types from Panuco; Dr. Eduardo Noguera supplied us with red on brown sherds from Xochicalco which Dr. George W. Brainerd suggested should be compared with Yucatán Red on Slate; and, while Shepard was in Mérida, Dr. Alberto Ruz gave her the opportunity to examine his Edzná collection, which is of interest in relation to Petén types.

Ceramic studies carried on in the laboratory generally raise questions regarding trade in pottery, its effect on the spread of techniques and styles, and its reflection of contacts between peoples. Often the material required to answer such questions can be obtained only by extensive survey and testing. It is therefore necessary to formulate our problems directly with reference to the materials which are being recovered through field operations. The work at Mayapán has not yet progressed far enough to outline broad technological problems, but acquaintance with field conditions and the relations observed among present-day potters of the region have clarified the problems of regional exchange in Yucatán and given us a sounder working basis.

4.20.

RAYMOND H. THOMPSON
Modern Pottery of Yucatán

YB 51:266, 1952

During the late spring and the summer of 1951 R. H. Thompson made a study of pottery-making among the present-day Yucatec Maya. Previous studies of this subject have emphasized the uniformity of the method of pottery manufacture in this area and have singled out the use of the *kabal*, a foot-turned, unpivoted wooden support for the vessel, as the most striking feature of the method. The present study was aimed at documenting as much ethnographic detail as possible in order to accumulate a body of data on pottery-making which could serve as the basis for inference to archaeological ceramic materials.

Every village where pottery was known to be made was visited. These were Uayma, Valladolid, Mama, Ticul, Maxcanú in Yucatán; and Becal, Tepakan, Campeche, Lerma in Campeche. Also visited were Mérida and Izamal, where pottery is known to have been made around the turn of the century, but no surviving potters could be located at either place. All the steps in the pottery-making process from the collection of materials to the firing of vessels were recorded. Particular effort was made to obtain a complete photographic record. As much of the total process as possible was observed and recorded at each village visited. Further information was obtained by interrogation. A fairly extensive Maya vocabulary of pottery terms was compiled. Samples of materials, implements used in the manufacture, vessels, and other pottery objects were collected in all the villages. The samples of clay, temper, paste, and paint were turned over to Shepard, who has begun a technological study of them.

In addition, several old collections of Yucatán pottery and pottery-making equipment were examined. The largest and best documented of these is in the Chicago Natural History Museum. It was obtained from potters in Izamal in 1895 by George F. Gaumer, who set down a very complete description of the pottery-making process as practiced there. There are a number of small collections in the Peabody Museum at Harvard University. The earliest-known modern vessels from Yucatán were collected for the Peabody Museum by Edward Palmer in Progreso in 1878 and by Alexander Agassiz in Mérida in 1882. E. H. Thompson made a collection of vessels and pottery-making equipment largely from Ticul in 1900. He also prepared a paper on Maya pottery-making, but failed to separate observation of contemporary manufacture

from speculation about the methods employed by prehistoric potters. Another small collection is in the University Museum at Philadelphia. It was made by Henry C. Mercer, who published several short papers on his observations of pottery manufacture in Mérida.

4.21.

ROBERT E. SMITH

Ceramic Studies in Yucatán

YB 57: 450–451, 1958

During the past season Smith's work embraced four main projects: a recheck of the ceramic material from Kabah, Uxmal, and Chichén Itzá, studied last season, and an integration of the results of the technological analysis of this material made by Shepard in 1958; completion of the recording of data on the pottery of Mayapán; the selection of Mayapán pottery types as material for sherd libraries for various institutions in the United States and Mexico; and the organization in cases of all the ceramic material to be turned over to the Instituto Nacional de Antropología e Historia of Mexico.

Since he had previously studied the material from Kabah, Uxmal, and Chichén Itzá, it was a simple matter to introduce and to coordinate the technological data found by Shepard. This new information added greatly to the understanding and description of the wares and types from these sites. For example, ash temper formed 66.5 percent of all tempers used in the sherds examined from the Toltec Phase at Chichén Itzá, as compared with 19.4 and 33.7 percent from the latest phase at Uxmal and Kabah, respectively. This predominant use of ash temper suggested a considerable deposit of that material at or near Chichén Itzá, and with this in mind Shepard checked the area briefly during a two-day visit to the site but found no evidence of ash. This fact does not, however, eliminate Chichén Itzá, or some place near by, as the source of the wind-blown ash used as temper, since Shepard had insufficient time to make a thorough search of the site and did not investigate the surrounding areas. Ash of wind-blown origin was used as temper, though to a lesser degree, in the Puuc area, at least on pottery pertaining to the latest phase at Uxmal and Kabah. It is possible, then,

that ash was employed somewhat sparingly by potters who had the material at hand during the Classic Period, and that the use was greatly increased during the Early Mexican Period in Yucatán, owing to the advent and influence of the Toltecs who dominated Chichén Itzá during that period. These Toltecs, coming from a volcanic region in Mexico, may well have been prejudiced in favor of ash temper.

Prior to this season Smith had made a careful study of the pottery associated with the earliest and latest deposits at Mayapán. This year his efforts were concentrated on the pottery found midway between the earliest and the latest levels. The middle levels at Mayapán contained a very substantial part of the total sherd material examined, and for that reason, as well as others, they are of great importance. The result of this work was that, in Smith's opinion, there is no identifiable middle ceramic phase. The early types extend into the middle levels, gradually diminishing, and the late types occur in small quantities, gradually increasing until in the surface levels they predominate.

The selection of Mayapán pottery to be sent to various institutions in the United States and Mexico involved seven types: Mayapán Unslipped, Mayapán Cream, Mayapán Black on Cream, Mayapán Red, Mayapán Red on Buff, Mayapán Red and Black on Buff or on Orange, and V Fine Orange. Examples of all of them, including most of the shapes, decorative techniques, and styles of design, were chosen for shipment to each institution.

The organization of the ceramic material in the Institution's laboratory in Yucatán was on a typological basis. This material, together with all other artifacts, will shortly be transferred by the Instituto Nacional to the recently formed Instituto de Antropología e Historia de Yucatán in Mérida. There are collections from 87 sites: Quintana Roo, 29; Yucatán, 21; Tabasco, 18; Campeche, 16; Chiapas, 2; Veracruz, 1. Of these collections the largest and most thoroughly studied are: from Yucatán-Mayapán, in which the types are arranged according to early, middle, and late levels, Chichén Itzá, Uxmal, Kabah, and Maní; from Quintana Roo, Tulúm, Ichpaatún, and Tancah; from Tabasco, Jonuta, Juárez, Tamulté, and Huimango; from Campeche, Atasta, Santa Rosa Xtampak, Xpuhil, and Dzibilnocac (Iturbide); from Chiapas, Tecolpan. A report on the pottery from Atasta, Huimango, Jonuta, Juárez, Tamulté, and Tecolpan has been published by H. Berlin. W. T. Sanders has prepared, and will shortly publish, a study of the collections from Calderitas, Ichpaatún, Tancah, and Tulúm. A report by R. E. Smith on the Early Postclassic Period or Toltec Phase pottery at Chichén Itzá and that of the latest ceramic period (Late Classic and Early Postclassic transitional) at Uxmal and Kabah is nearing completion, and a full

report by the same author on the pottery of Mayapán is under preparation. Last, a general study by the late G. W. Brainerd of the pottery of Yucatán, which will include most of the Yucatecan sites in the collection, is expected to appear in the near future.

4.22.

ANNA O. SHEPARD

Ceramic Technology

YB 57: 451–454, 1958

During the current year Shepard, working in a half-time basis, has reviewed technological data on Yucatán and lowland Maya pottery in order to prepare this material for publication while transferring to geology and her major field of endeavor. Much of our analytical work on the ceramic technology of these areas was undertaken before the archaeologist's stylistic studies were completed. Our principal need, therefore, was to round out our data and establish a broader base for interpretations. This necessitated study of collections in Yucatán and Guatemala.

Shepard spent 12 weeks in the field seeking correlation between stylistic and technical features. From January 10 to February 7 she worked in Mérida on R. E. Smith's collections from test cuts at Uxmal, Kabah, and Chichén Itzá. A clear cut distribution pattern and definite relations between paste composition, ware, and vessel shape emerged from this review. Some wares, such as the fine-textured, calcite-tempered Thin Slate and the coarse, sherd-tempered Holactún Black on Cream, are uniform in composition, whereas the more generalized ware Puuc Slate is heterogeneous, including four paste classes: calcite-, volcanic ash-, and sherd-tempered pastes, and lumpy untempered paste. A number of varieties of calcite temper further diversify this ware. A similar contrast is found in the stylized vessel shapes. Calcite-tempered or volcanic ash-tempered paste is strongly preponderant in some forms, whereas others include a significant representation of the main paste classes. The degree of paste uniformity also differs by site. The two classic Puuc sites, Uxmal and Kabah, have a heterogeneous paste representation; in contrast, the Chichén Itzá sample, classed as Toltec by Smith, is exceptionally uniform, the various slipped types running almost exclusively to volcanic ash temper and the unslipped types to cal-

cite temper, with high correlation between classes of calcite and vessel form. We have, then, some good correlations between paste, ware, and shape, some centers showing well established techniques, others exhibiting technical diversity. These occurrences are most simply explained by the hypothesis that pottery-making communities drew on diverse local resources and that there was a lively trade among them, some communities being much more dependent on exchange than others. That is, standardized wares and types may be considered products of pottery-making communities having well established techniques; classes that are variable in composition suggest that style was more widely established than technique; uniformity within a site may reflect self-sufficiency in pottery production; diversity may indicate a community depending in large measure on trade for its pottery. These explanations are without doubt glaring oversimplifications. There are other factors that must be weighed, especially exchange of raw materials, potters of a community practicing a number of different techniques or passing through a period of experimentation, and different degrees of standardization in different centers. These explanations should all be tested as working hypotheses in future explorations, and this season's results hold promise that definitive answers can be obtained.

Several collections from other sites were examined for comparative purposes. The most interesting was a small sample of Tulúm Red Ware. Its calcite-tempered paste was distinguished from this class of paste in the Puuc sites, Chichén Itzá, and Mayapán by the presence of quartz grains. This diagnostic served to identify as trade ware some of the sherds from a small Mayapán lot selected by Smith on the basis of surface features as possibly Tulúm Red.

While in Mérida, Shepard examined a sample of the principal wares and some unusual pieces from the National Geographic-Tulane University excavations at Dzibilchaltún. It was gratifying to find sufficient interest in the results to give promise that this line of investigation will be followed independently.

Two pottery-making villages, Lerma and Tepakan, were visited to observe firing methods, and a record of firing temperature was obtained from the work of a Ticul potter at Hacienda Uxmal.

An attempt to obtain information on the source of the pigment Maya blue and to get a sample of it from the village of Tekax, where it is rumored to occur, was unsuccessful. During the year, however, additional analytical data on this pigment were secured. A record of reflectance spectra was made through the courtesy of Dr. R. O. Fehr, of the General Electric Company. The tristimulus values calculated from such curves serve to identify pigments, but no published values corres-

ponding to those obtained for Maya blue have been found. Shepard has considered the possibility that this pigment is an organic dye held by a clay with an expanding lattice. It was hoped that a clue to the presence or absence of an organic constituent might be obtained from an infrared transmission spectrum. Dr. Hans B. Gottlieb and Mr. Bert Weberg, of the Chemistry Department of the University of Colorado, kindly ran spectra for Maya blue and hematite as a control. The Maya blue curve corresponded to that of a rare clay mineral, but one peak, which might represent an organic constituent, was too faint to be definitive. A dye, if present, would make up a small percentage of the material, and we are still handicapped by lack of an adequate sample.

In Guatemala from February 7 to March 30 Shepard's principal project was a re-examination of the Uaxactún collection. She had established the sequence of paste classes in previous seasons. It is surprising that sherds, a superior tempering material that predominated in Mamom ware, was replaced by the inferior material, calcite, for unslipped Chicanel ware, and in the following phase, when ceramic progress was expressed by the advent of polychrome ware, sherd temper was abandoned almost completely. It was in the Tzakol phase that volcanic ash was first used extensively, and the great bulk of early and middle Tepeu fine ware was tempered with this material. Unlike the volcanic ash of Yucatecan ware, this shows considerable diversity in texture. Especially noteworthy is the associated mineral matter, which is high enough in one variety to class it as a crystal-vitric ash. It seems improbable from the coarseness of the ash that it was air borne this distance. The sources of these ash tempers of the Petén are as yet undetermined. Geologists from a number of oil companies having concessions in the Petén were interviewed but could offer no clues.

Correlations between paste composition and defined style were not high, suggesting that Uaxactún potters were using a variety of pastes indiscriminately or that Uaxactún was obtaining pottery from an area in which a single stylistic tradition held but technique and resources differed, or that our sherds were not giving adequate stylistic criteria. When attention was directed to finishing techniques, color classification previously established was found inadequate. It had not been related to basic finishing method and was sometimes misleading because the colors of distinct slips often intergrade and a given slip may exhibit wide color variations depending on post discard environment. The fullest evidence was obtained from the painted wares of the Classic Period. There are two distinct classes of slip: one is whitish to buff, earthy, nearly lusterless, and was applied as a relatively thick coat;

the other, which ranges from yellow through orange to red, has a high lacquer-like luster and is very thin. Frequently, both these materials are used on the same vessel, the lustrous one always forming the final coat. Each, however, was also used alone, and a fourth technique consisted in smoothing and polishing without the application of a contrasting coat. Microscopic examination has further broken down the light slip into calcareous, noncalcareous, and ash-tempered varieties. The composition of the lacquer-like coat remains to be defined by laboratory analysis. These four basic finishing techniques are primary diagnostics and in a number of instances showed close correlation with style and paste.

Two outstanding features of Classic Petén decoration are the range of colors obtained by mixing pigments and specialized resist techniques. Pigment mixtures include gray from manganese and calcite, a lavender pink from hematite red and calcite, and brown from manganese and hematite. The constancy of color of the brown, which was used to represent body color in figure painting, indicates the maintenance of similar proportions of the two pigments. A striking feature of the resist decoration is the employment of hematite red paint in contrast to the carbon black which is the standard pigment for this type of decoration in both North and South America. Evidence was also found for two successive applications of the resist material and the use of two colors in the resist process itself, which reflect an unusual elaboration of this specialized technique.

Other collections examined for comparative purposes included that from Piedras Negras, which presents marked uniformity in paste composition in contrast to Uaxactún. Shepard also spent two days at Tikal examining a sample of the pottery and reviewing the problems of paste analysis for Miss [Vivian] Broman, of the University Museum. A small collection of special interest was that made by Dr. Willey, of the Peabody Museum, at Altar de Sacrificios, a site long suspected of being a trade center. A number of pastes were defined, the sources of which cannot at present be located because of our limited knowledge of distributions in this area.

Short trips were made to Zaculeu, with a stop at Quezaltenango to examine the Robles Collection from Finca Paraiso, and to Cahyup near Rabinal. The latter trip indicated the feasibility of attacking the problem of trade and centers of pottery manufacture by defining petrographic provinces. Cahyup is in the Precambrian, well beyond the region of recent volcanics. The pottery reflects this location. Schist or quartzite was present in the three classes of paste collected. The location of petrographic provinces would be guided by available geologic maps and, in collecting, due atten-

tion would be given to the smaller sites which may have relatively less trade ware than the large prominent ones. This approach seems worth pursuing.

In bringing the Ceramic Technology Project to a

close Shepard will concentrate on the completion of reports. She will also be glad to aid, in whatever way is feasible, students interested in taking up any aspect of technological analysis.

5.0. TEXTILES

5.1.

LILA M. O'NEALE

Guatemala Textile Investigations

YB 35:136–138, 1936

It is unlikely, because of climatic conditions, that any representative group of textiles or other perishable materials dating from pre-Colombian periods in Guatemala will ever be recovered. It is, therefore, chiefly inferences based on surviving fundamental techniques that the artistry and the very evident technical skill of the old weavers as shown in the carvings must be interpreted. There are no such elaborate costumes extant today as were worn in the prehistoric periods, but unless new tools and obviously introduced devices be found, it seems reasonable to believe that some of the ancient methods of making fabrics are still in use.

The investigation carried on by Dr. O'Neale during the first half of the year had the following objectives: to visit the highland centers of weaving; to study the methods of producing cloth from native and imported materials; to study the use of simple sticks and more or less crudely shaped tools; to analyze the seemingly complex techniques in terms of skills with which those tools have been adapted to variety of pattern requirements. Mat-making and basketry were arbi-

trarily eliminated, as fabrications of materials which do not require spinning.

The methods of gaining data and information were direct. If possible, the market of a center was visited several times. Whenever details of clinical interest or of patterning were noted, efforts were made to find men who knew how to weave the specific features shown by the fabric. Special orders involving the duplication of the features were then given usually with the stipulation that they were to be executed in the presence of the investigator. The general territory covered may briefly be characterized by centers:

1. The Guatemala City-Antigua area: This district represents artistic rather than technical diversity. The typical patterning depends upon some of broadcasting, in the main.
2. The Tecpán area: The costumes from several smaller centers show techniques ranging from heavy brocading to sketchy embroidery. In the two areas mentioned there is an increasing amount of work

- being done by professional weavers of certain villages. The logical development out of a tendency toward specialization seems to be the purchase of factory materials and complete independence of the product of hand looms. Most of the Indian men's costumes have reached the point where the *banda* or sash is the sole remnant of hand weaving.
3. The Lake Atitlán area: The costumes in this part of the highlands are simple, the techniques are fundamental, and the conventional pattern entails little in the way of individual ingenuity.
 4. The Chichicastenango area: Here the complexity of the standard designs woven in silk, wool, or cotton by the woman, and the elaborate embroidery in silk on heavy home-spun black wool garments by the men are the main features of the textiles. The men's work, because still done for themselves, remains of higher quality, in general, than the women's weaving which has noticeably deteriorated during the last two years. This is an expectable result of a demand for trade products in primitive communities.
 5. The Momostenango area: This is the region celebrated for its work in wools, its dyeing with natural dyes, weaving in fundamental as well as eccentric patterns, and felting. While the spinning and weaving are done almost entirely with appliances derived from Europe, dyeing and felting are still accomplished by simple methods known to be used by primitive craftsmen in other parts of the world.
 6. The Quezaltenango-Salcajá-Totonicapán area: From the standpoint of methods and production, this area is unusually rich. There are still a number of small pueblos in which all the materials for the women's huipiles, and even some of the men's garments, are made on back-strap looms. There are, too, in this district, masses of materials made on foot-power hand looms, and on draw looms like those which preceded the Jacquard. In addition to the hand-loom products, there are the increasingly available materials coming steadily from the modern factory at Cantel. Salcajá supplies a large percentage of all the skirts which have patterns in tied and dyed yarns. Embroidery is done professionally by women, especially those of San Cristóbal Totonicapán.
 7. The San Pedro Sacatepéquez (Departamento de San Marcos) area: This center is a smaller Quezaltenango in the type and quantity of fabrics which come from its looms. Yet, side by side with yardage output, there may be found the weaving of huipiles by the women on their back-strap looms.
 8. The Cobán-Salama-Rabinal area: The costumes in this district are simple, but the techniques represent a high degree of skill. This is the only highland region in which gauze weaving is typical. The handling of fine single-ply cotton yarns in two varieties of the gauze weave says not a little for the manual skill of the weavers of the district. Also, besides the thin brocaded fabrics, there are the elaborate heavy brocades of Tactic, and the delicate embroidery of Cobán, at this time usually executed on factory made materials.
 9. The Huehuetenango area: This pueblo is the market center for a district rich in various types of hand weaving with both cotton and wool yarns. Unfortunately, unless one is prepared to go on beyond automobile roads, there is little in the way of actual result to be gained from a visit. Some of the most interesting fabrics in Guatemala come from the area bounded on the south by Comitancillo and on the east by Sacapulas. Because of the comparative isolation of the villages within this rectangle, there should be remnants of techniques which have persisted over a long period of time.

The textile fabrics of today in the Guatemala highlands are not technically complex, but they do show distinct local variations. The simple back-strap loom may be held responsible for the several modifications of the plain over-one-under-one weave, many types of weft-face brocades, several standard twills, and the gauzes. There are also warp-face pattern materials, and pile-loop weaves. Of the eight standard weaves known through modern fabrics, only the satin and the double-cloth are missing. The materials used are cotton, rarely hand-spun in these days, wool, silk of different qualities, and a deplorably increasing amount of artificial silk.

6.0. HIEROGLYPHIC WRITING

6.1.

SYLVANUS G. MORLEY AND
J. ERIC S. THOMPSON
Hieroglyphic Research

YB 32:97–98, 1933

Dr. Morley devoted such time as he could spare from administrative duties to completion of his monograph *The Inscriptions of Petén*, second of the compendious treatises in which he plans to cover the entire field of Maya monumental epigraphy. The first, *The Inscriptions of Copán*, appeared in 1920; the third will include all sites not considered in the first two. It is believed that the Petén volumes will go to press in 1934. The preparation of the many maps, plans, drawings and photographic plates has required periodic visits by Dr. Morley to Washington, where, under the able and painstaking supervision of Mr. T. R. Johnson, this great body of material is being prepared for the lithographers and engravers.

Mr. J. Eric Thompson, on leave from the Field Museum of Natural History, spent half a year in hieroglyphic research under auspices of the Carnegie Institution. His work consisted of an examination of the notes left by the late Research Associate of the Institution, Dr. John E. Teeple, at the time of his death, and of

the mathematical testing of glyphs whose meanings are unknown.

Dr. Teeple's material, kindly loaned to Carnegie Institution by Mrs. J. E. Teeple, proved to be almost entirely calculations without explanatory notes, the great majority evidently having been made for his publication, "Maya Astronomy." Almost all the residue dealt with the application of the determinant theory to Maya dates at various cities. Unfortunately, it would appear that the subject matter of the publication which Dr. Teeple had in view at the time of his death was never committed to writing and, except for a few notes, has perished with him. It is unnecessary to emphasize the great loss to science that this entails.

Dr. Teeple's material was incorporated into a general survey of the application of his determinant theory to each city.¹ The incomplete results suggest the feasibility of a correlation between high mathematical ability and low artistic ability in certain cities. For instance, in accuracy of determinants Naranjo ranks very

high, yet the art of this city was always provincial and stiff. On the other hand at Yaxchilán, where Maya art reached its apogee, the determinant theory largely breaks down. Where the level of art is high, there is a tendency to frequent mistakes in the inscriptions and indifferent calculations. At Copán, however, where the art was definitely masculine, as opposed to the somewhat effeminate art of the cities of the Usumacinta Valley, accuracy and a high artistic standard go hand in hand. Results of the work upon determinants will probably throw light on the relations between different cities. For example, in the early period before 9.15.0.0.0 the determinants at Palenque and Copán are in pretty close agreement, calculating the interval from Cycle 13 at about two days more than Gregorian. At 9.15.0.0.0 Copán started to calculate at one or two days less than Gregorian; Palenque had, apparently, ceased to erect epigraphic monuments; while Naranjo as early as 9.12.0.0.0 was reaching the same accuracy as Gregorian, but in the later dates around 9.17.0.0.0 had turned to the old Palenque-Copán formula.

In the mathematical testing some 20 glyphs were chosen. In each case every known example from the monuments was noted, together with its position in the tropical year, distance in days from the mythical start of the calendar, and year-bearer under which it fell. The distances in days between all examples of each glyph were then calculated and the results submitted to every mathematical combination which it was thought the Maya might have employed. These included all astronomical figures, such as revolutions of the planets, but not the sidereal revolutions, which it would seem almost incredible that the Maya could have realized. The yearbearers under which each example fell were also examined for indications of any ritualistic grouping.

The results were disappointing. One group led to the hope that it might comprise seasonal glyphs, possibly gods ruling over 13 divisions of the tropical year, forming a kind of zodiac, but the evidence is not conclusive. Nevertheless this method holds out the best hope of learning the meanings of unknown glyphs; and its findings will be universally accepted since they can be shown to be mathematically correct. A publication incorporating the determinant material is now in course of preparation. In it will be embodied a discussion of the Venus glyphs.

NOTES

1. A determinant is any date which the Maya appear to have used to declare what addition should be made to the Long Count in order to bring any specified date in the 365-day year into the same relation with the tropical year as it was believed to have possessed at the mythical start of the calendar at 13.0.0.0.0, 4 Ahau 8 Cumhu.

6.2.

SYLVANUS G. MORLEY

Hieroglyphic Research

YB 42:178, 1943

Dr. Morley spent the summer of 1942 in Santa Fe, New Mexico, with offices at the Laboratory of Anthropology, where on June 1 he began the writing of a popular book on the Maya civilization, *The Ancient Maya*. He returned to Mérida, Yucatán, September 1, and has since been devoting his time to the completion of the book, which he finished early in June 1943. During the fall, winter, and spring he made a number of trips to Uxmal and early in May visited the newly founded Museo Arqueológico, Etnográfico e Histórico del Estado de Campeche, at Campeche, a splendid local institution.

Work on the hieroglyphic dictionary has gone forward. All Initial Series introducing glyphs at 39 sites (Copán and the 38 sites covered in Dr. Morley's study, *The Inscriptions of Petén*) have been drawn to scale, each on a separate card. Work has been commenced on another section of the dictionary, that presenting all known examples of Glyph C of the Supplementary Series.

In cooperation with the Instituto Nacional de Antropología e Historia of the Secretaría de Educación Pública, the Campeche Museum has been excavating the ruins of Edzná, an extremely important site in central Campeche which has close affiliations not only with the Old Empire but also with the Puuc Period of the New Empire. Three new Initial Series were discovered, as follows: Stela 18, 9.12.0.0.0, 10 Ahau 8 Yaxkin; Stela 19, 9.13.0.0.0, 8 Ahau 8 Uo(?); and a third, a fragmentary one, inscribed on the risers of the hieroglyphic stairway leading to the principle temple.

Mr. Alberto Ruz Lhuillier, of the Instituto Nacional de Antropología e Historia who was in charge of the excavation at Edzná assisted by Mr. Raul Pavón Abreú, Director of the Campeche Museum, spent a week studying the Institution's ceramic sherd collections in Mérida toward the end of May.

6.3.

SYLVANUS G. MORLEY AND
J. ERIC S. THOMPSON

Reconnaissance in Mexico and Guatemala

YB 43:169–172, 1944

Dr. and Mrs. Morley visited Copán in February 1944. During Dr. Morley's stay he made observations on all the 41 stelae known at that site for the purpose of comparing the coefficients of Glyphs C and X of their respective Supplementary Series in an endeavor to ascertain the cause of their observed interdependability. A new stela (no. 28), discovered by Mr. Strömsvik, was studied. This is only a fragment but presents a very early style of glyphs. Unfortunately it gives no date. The most important discovery of the trip was the identification of a heretofore unreported Initial Series. This was found sculptured on the south jamb of the west doorway of Temple II, and records the date 9.17.2.11.16 (A.D. 783).

Later in February Dr. and Mrs. Morley met Mr. and Mrs. Thompson at Tuxtla Gutierrez and together they visited sites in the highlands of Chiapas. At Chinkultic there was discovered a new Early Period stela (the tenth at this site) bearing the Initial Series date 9.9.15.?? (A.D. 628). This monument is important in that it carries the sequence of dates back a century and a half beyond the earliest previously reported at Chinkultic.

The party then moved to Toniná. This, the largest known Maya site in the Chiapas highlands, is beautifully located on the north side of the Jatate Valley, a range of low hills having been terraced and utilized for the erection of pyramids and temples clear to the summit, some 300 feet above the valley floor.

The most important epigraphic discovery was an Initial Series inscribed on the back of a crouching anthropomorphic figure of heroic size (Sculpture T.10). This may record the date 9.3.0.0.0 (A.D. 495), which is 60 years earlier than any previously reported at Toniná. Two new Period Ending dates were also deciphered: 9.12.5.0.0 (A.D. 677) on Sculpture T.17, and 9.15.0.0.0 (A.D. 731) on Sculpture T.34.

Toniná was evidently a city of considerable importance. The style of its sculpture strongly suggests connections with the great cities of the Usumacinta valley, Piedras Negras, Yaxchilán, and Palenque, the one hand, and with Copán and Quiriguá in the south-east on the other.

On his return to Guatemala City in mid-March, Dr. Morley went to Quiriguá to compare the coefficients of Glyphs C and X of the Supplementary Series on the monuments of that site. On March 28 he flew to Flores,

capital of the Department of Petén, accompanied by Mr. Virgilio Viscovich, of the Chicle Development Company, whose services had kindly been loaned to the expedition by Mr. Cloyd Smith, manager of the company in Guatemala, without whose timely and powerful assistance the expedition could not have covered so much ground in Petén in so short a time. Mr. Smith, in addition to permitting Mr. Viscovich, to accompany the expedition as transport manager, not only placed at its disposal a powerful outboard motor for river travel, but also provided Dr. Morley with letters of recommendation to the company's contractors throughout Petén.

The expedition continued on to La Libertad in the great central Petén savanna by automobile the same afternoon, and the following day, again by automobile, to Paso Subin on the Río Subin, a small tributary of the Río de la Pasión. Here the party embarked in a dugout canoe, temporarily equipped with an outboard motor, for the trip down the Río Subin and Río de la Pasión, and reached La Florida late the same night.

The next morning Dr. and Mrs. Morley visited the nearby ruins of La Amelia, 5 miles [8.1 km] distant, first reported by Messrs. Pollock, Smith, and Shook of the Division's staff in the spring of 1940; and continued down the Río de la Pasión, reaching the important site of Altar de Sacrificios, 3 miles [4.8 km] above the mouth of the river, that evening.

Altar de Sacrificios is located on the point of land between the Río de la Pasión and the Río Salinas, which unite, 3 miles [4.8 km] below, to form the Río Usumacinta, the largest watercourse in Central America. This site in ancient times must have been of considerable importance because of its strategic location. Upriver, six to ten days by canoe, would have brought the Maya to where they could reach Quiriguá in two days' journey by mountain trails, and within three days' journey of Copán. Three days up the Río de la Pasión and the Río Subin, and another three on foot through the forests and savannas of central Petén, would have brought them to Tikal, the largest city of the Old Empire, and, a day beyond, to Uaxactún in northern central Petén. Six to ten days up the nearby Río Salinas would have put them in the important centers of the Guatemala highlands; six to ten up the nearby Río Lacantún, a tributary of the Río Usumacinta, brought them to the various centers of the Chiapas highlands. Finally, it required but two to three days' journey down the Río Usumacinta to reach Yaxchilán, Piedras Negras, and Palenque, the greatest art centers of the Maya. Literally, Altar de Sacrificios lay at the crossroads of the Old Empire.

Here Mrs. Morley discovered three new stelae and three new altars, the former numbered 15, 16, and 17. Two new Initial Series were found: 9.3.0.0.0 (A.D. 495)

on Stela 13 and 9.10.?.?.? (between A.D. 633 and 652) on Stela 16; and two new Period Ending dates: 9.14.10.0.0 ? (A.D. 720 on Stela 2 and 9.15.0.0.0 ? (A.D. 731) on Stela 17. Most significant, however, was the correction of Dr. Morley's former readings of the Initial Series on Stela 10 and 11 from 9.7.10-0-0 (A.D. 583) to 9.2.0.0.0 (A.D. 475). This extends the sequence of dated monuments at Altar de Sacrificios backward some 50 years and, indeed, makes this site, on the basis of the dated remains, 40 years earlier than any other known city in the Usumacinta Valley. It raises the implication, moreover, that Maya culture reached the Usumacinta Valley by way of the Río de la Pasión and thence down the Pasión Valley, rather than via the Río San Pedro Martir in northwestern Petén and thence up the Usumacinta Valley, as Dr. Morley formerly believed.

The expedition left Altar de Sacrificios for the return journey up the Río de la Pasión on April 3, stopping at La Florida to visit the nearby ruins of El Caribe, discovered by Messrs. Pollock, Smith, and Shook in 1940, and the ruins of Aguas Calientes, discovered by Drs. Morley and Spinden in 1914. The next afternoon La Libertad was reached, and the following morning was spent at the ruins of Polol, some 8 miles [12.9 km] west of La Libertad, first reported by C. L. Lundell, of the Institution's botanical expedition to Petén in 1933.

Dr. and Mrs. Morley flew from Flores to Paso Caballos on the Río San Pedro Martir on April 11, where they were met by Mr. Salomon González, the Chicle Development Company's contractor at La Florida on the middle reaches of that river, a few miles east of the boundary between Mexico and Guatemala. In March 1943 Mr. Shook had reported an important new site with sculptured stone monuments on the south bank of the Río San Pedro at La Florida, which was reached by motor-driven dugout canoe from Paso Caballos on the morning of April 12. The ruins are located immediately behind the present chicle and rubber camp. Four new stelae were discovered; one new Initial Series, 9.15.0.0.0 (A.D. 730 on Stela 9, and one new Period Ending date, 9.16.15.0.0 (A.D. 766) on Stela 7.

The party left La Florida late the following afternoon by canoe downstream. The Guatemala frontier guard at Progreso on the north bank of the San Pedro River was passed the same night, and late the following day the expedition reached the small settlement of El Tiradero, Tabasco, Mexico, at which point the newly opened railroad from Tenosique to Campeche, Mexico, crosses the San Pedro. The next morning Dr. and Mrs. Morley left El Tiradero by rail for Campeche, and reached the latter point the same evening and Mérida the following day.

6.4.

J. ERIC S. THOMPSON
Hieroglyphic Research

YB 43:172-173, 1944

The elucidation of the purely numerical part of Maya hieroglyphic writing has progressed so far that the possibilities of further success along those lines continually diminish. Recently Mr. Thompson has attacked the problem from a different angle, that of seeking parallels between the hieroglyphic texts and the chronological sections in the Books of Chilam Balam. There is a certain danger in that approach because we are not certain exactly what language was spoken by the people who erected the stelae. One may assume, however, that the language was some lowland dialect, because the highland Maya did not erect stelae with hieroglyphic texts. Unfortunately there are no chronological passages in Tzeltal, Chol, or neighboring lowland dialects or languages, but these are fairly close to Yucatec, the language of the Books of Chilam Balam.

A start has been made in deciphering the many affixes attached to the hieroglyphs. Mr. Thompson has identified the affix corresponding to the Yucatec preposition *ti*, "at, on, or from," and elements indicating backward and forward. He has also advanced evidence that the symbol for counting was the figure of the mythical fish called *xoc*, because this and the Yucatec word *xoc*, "count," are homonyms. This is the first good evidence that the Maya used rebus writing. The results of these investigations were published early this year under the title "The fish as a Maya symbol for counting." Since the publication, of that paper Mr. Thompson has come upon other material confirming beyond reasonable doubt his identification of the fish symbol as the *xoc* fish.

A variant of the affix used as the preposition *ti* appears with fair frequency in Maya inscriptions. Its occurrence in Yucatecan texts before the coefficients of month signs indicates that it represents the word *tu*, a contraction of *ti* and *u*, "of," for in the Books of Chilam Balam *tu* is written before the day coefficient, for example *ox cauac tu hunte pop*, 3 Cauac at first of Pop. Here glyphs and words are in complete accord.

Another example of rebus writing is supplied by the completion sign, which consists of a hand over a moon sign and which, immediately precedes the period ended. Here the moon sign can have no lunar significance, but *u*, the Yucatec word for moon, also means "of." The combination almost certainly reads *u dz'ococ* "the 'completion' of," for this expression oc-

curs frequently in the books of Chilam Balam in connection with Period Endings.

Sometimes the hand is shown in the act of scattering grain, with the *xoc* bracket "count" as prefix. In this form the glyph usually follows a record of time completed or precedes the day on which it was completed. It is not improbable that here we are dealing with a past participle *dz'ocaan* means, "brought to completion," and *ocaan*, "sown." One may assume that there is partial duplication here, such as occurs in Aztec rebus writing. For instance, the Aztec glyph for the town of Cuahuacán is composed of a tree, an eagle, and the place symbol, but the first two elements, *cuahitl* and *cuauhtli*, "tree" and "eagle," duplicate each other, one being redundant except to confirm the reading of the other. The Maya glyph, then, would read *xoc dz'oc (oc)aan*, "the count brought to completion."

Confirmation of the translation of one prefix as "forward" is supplied by its further use as prefix to an element which enters into the combination Teeple translated as "new moon" or "same moon age." Actually, the glyph has a somewhat wider meaning, for it is used to indicate that the date to which it is attached has lunar significance. When the forward prefix is added, the whole indicates that it is the later of the two dates between which it lies which has a lunar significance. This form occurs only at Palenque, where it was particularly needed because of the involved order in which dates and distance numbers were often recorded. Another affix is placed below period glyphs only when they occur as distance numbers.

Among the present-day Maya of the Guatemala highlands who still retain the old Maya almanac of 260 days, sunset marks the start of the new day. For Yucatán we have no direct evidence as to when the day started, but certain passages in the books of Chilam Balam suggest that the division came at day-break or sunrise. A study, involving mythological concepts, of all variants of the glyph for day in Maya texts leads to the conclusion that the glyphs record a count by sunrises. It is, of course, possible that the starting point had shifted from dawn to dusk before the Initial Series period, but that the old terms had survived in speech and writing just as September etc. have survived in our calendar, although they are no longer the seventh *et seq.* months.

The time may not be far distant when Maya hieroglyphic terms will have to be translated first into Maya in order to conserve the full richness of their message.

6.5.

SYLVANUS G. MORLEY

Hieroglyphic and Historical Research

YB 44:170–172, 1945

Dr. Morley left New Orleans for Mérida, Yucatán, Mexico, on November 7, 1944, returning there from on May 3, 1945. He spent the summer, at Santa Fe, New Mexico, his usual summer headquarters, where Dr. E. L. Hewett, Director of the School of American Research and the Museum of New Mexico, very kindly placed at his disposal office quarters in the Palace of the Governors at Santa Fe, now the Museum of New Mexico. He will return to Yucatán at the beginning of November.

Dr. Morley has devoted the year to two principal research activities: preparation of the Maya hieroglyphic dictionary, and work on the Maya chronicles, in the Book of Chilam Balam.

For work on the hieroglyphic dictionary, a full-time draftsman, Mr. Isaac Esquiliano, of Mérida, has been continuously employed for the past three years, drawing the individual glyphs of the Maya stone, stucco, and wood inscriptions under Dr. Morley's direction and supervision. During this period Mr. Esquiliano, a Mexican of mixed Spanish and Maya descent, has developed a very high degree of skill in drawing the Maya glyphs.

At the beginning of this enormous task it was decided to draw first all the glyphs of known meaning, and later those of unknown meaning. Further, in order to facilitate accurate representations, it was decided to concentrate on one glyph at a time, drawing all known occurrences of this particular glyph before proceeding to another. In this way, in the case of partially effaced and badly eroded glyphs, the draftsman would have the benefit of previous, experience and familiarity with better-preserved examples of the same glyph.

The first section of the dictionary is thus devoted to the Initial Series introducing glyph, a highly important character in the Maya inscriptions, which not only stands at the head of most inscriptions where it occurs, but whose principal element indicates the name of the patron deity of the Maya month in which the accompanying date falls. This first section is about finished, barring a few odd examples of this sign, chiefly in inscriptions from Campeche.

The next eight sections of the dictionary are being devoted to the different examples of Glyphs G and F of the Initial Series and to the six different signs of the Supplementary Series, Glyphs E, D, C, X, B, and A, all of which deal with the moon. Of these, the examples of Glyphs E, D, C, and X are also nearly completed.

The drawings of the different occurrences of Glyph D have brought to light important new variants and have made possible a number of corrections in decipherment of the corresponding moon ages expressed by that character.

With the cumulative experience gained in repeatedly drawing the same glyph, we have been able to get more out of partially effaced inscriptions than was formerly possible, and although only a beginning has been made, the project may be said to be off to a good start.

The Maya Chronicles Project deserves a brief word of introduction. There have been preserved in certain native Maya manuscripts known as the Books of Chilam Balam, which are written in the letters of Spanish script but in the Maya language, five chronicles or rescripts of Maya preconquest history. These chronicles are of varying degrees of merit, and there is strong internal evidence that three of them have been copied from a single source, probably an ancient Maya historical manuscript in the hieroglyphic writing, the original of which is now either lost or destroyed.

These five chronicles contain practically all that has survived on the documentary side (that is, as opposed to the stone, stucco, and wood inscriptions) of ancient Maya history. Laconic as the chronicles are, they nevertheless present a fairly accurate picture with a solid chronological background of the main events of Yucatán history from the early fifth to the late seventeenth century; and, as primary historical source material of the very highest importance, they have long merited the exhaustive and critical study now being given them by Dr. Morley and Dr. Alfredo Barrera Vásquez.

Dr. Barrera Vásquez is now working under a grant from the Colegio de México but having formerly held both Guggenheim and Rockefeller fellowships, has been collaborating with Dr. Morley on a definitive translation of these Maya chronicles into both Spanish and English, and on an interpretive study of their contents.

For the past decade, under the auspices of the above agencies and others, Dr. Barrera Vásquez has been devoting a major portion of his time, first, to making a reconstructed text, filling the lacunae in one chronicle from another and including all variant versions; and, second, to translating the original Maya into Spanish. For the past two years he has spent a month in Yucatán each spring working with Dr. Morley on this investigation. The Barrera Vásquez reconstructed Maya text of the chronicles has been translated directly into English, which language, it has been found, renders the original Maya more exactly than does Spanish. Dr. Morley has written a commentary on the chronicles, incorporating therein the results of his own epigraphic studies during the past 30 years in

so far as the latter concern the course of ancient Maya history in the northern half of the Yucatán peninsula.

The history of Yucatán, as set forth in the Maya chronicles, begins with the discovery of the province of *Ziyancaan Bakh'alal* (the region around the modern Lake Bacalar in southeastern Yucatán) by a group of ancient Maya called the Itzá, probably proceeding from some Old Empire site in what is now northeastern Petén, Guatemala, in 9.0.0.0.0, 8 Ahau 13 Ceh of the Maya era, or A.D. 435, and closes with the fall of Tayasal, the last Itzá capital, in central Petén, in A.D. 1697, more than 12.5 centuries of documented Maya history.

6.6.

J. ERIC S. THOMPSON
Hieroglyphic Research

YB 44:172–173, 1945

In the previous report a brief description was given of a new approach to the problem of the decipherment of the Maya hieroglyphs. This method, which involves comparison of glyphic texts with the content of the Books of Chilam Balam, continues to yield interesting results.

In the various Books of Chilam Balam occurs the expression *u xoc'ol haab ti lak'in*, "the count of the year to the east," and one may safely assume that similar phrases involving the other world directions were current in Yucatán in the sixteenth and seventeenth centuries. In the hieroglyphic texts of the monuments, the four world direction glyphs are frequently followed by a glyph which consists of an element previously identified as a symbol for counting, and the sign for year. The whole is surmounted by a well known superfix of unknown meaning. There can be no doubt that these pairs of glyphs mean. "To the east [north, west, or south] the count of the year." The whole supplies a close parallel to the Books of Chilam Balam save that the world direction is given first, not last.

A problem which has vexed Maya archaeologists for some 50 years is that of the meaning of the "pectacle glyph" which is attached to month signs on occasions which can be proved arithmetically to fall the day before the first day of a month. This sign has been generally read as zero. There are two serious objections to

this reading. First, signs with a meaning approximating that of zero are known, but are never substituted for the spectacle glyph. Secondly, the spectacle glyph is combined with the Winged Cauac (the *haab* or year sign), which, if the interpretation as zero were correct, could only mean zero approximate years. There are cases, however, where this glyph with dates which end 13 approximate years. The interpretation is thus obviously at fault.

In the Books of Chilam Balam one frequently finds, the phrases *u cutal Pop*, *u cutal Uo*, etc., "the seating of Pop," "the seating of Uo," etc., set opposite the first day of each month. On page 7 of the Chilam Balam of Tizimin is the expression *ti cutal ti tun*, "at the seating of the approximate year." Interpretation of the spectacle glyph as "the seating of" fulfills all the demands of the various contexts, and agrees with Maya phraseology. This interpretation led to the identification of two new glyphs, variants of the spectacle glyph, which record whether the addition of a distance number leads to the end of a tun or merely to an odd day. The glyphs must mean respectively "[leading] to the seating of the tun" and "[leading] to the seating of the day." More and more evidence accumulates that the hieroglyphic texts closely, parallel the spoken word.

Little success has hitherto attended efforts to interpret affixes, and variations in those attached to glyphs of known meaning have for the most part been ignored, or dismissed as artistic variations. As an example of slight variations in meaning which they reflect one might cite the three common suffixes of period glyphs. The geometric forms of the katun and tun usually stand on three small circles when these glyphs occur in Initial Series or as period endings. When these glyphs (and other period glyphs) are used as distance numbers, the suffix takes the form of two or three circles between two inverted crescents. Thus, if one finds a period glyph with this form of suffix, one knows that it is part of a distance number. Rarely, the simple suffix of three circles is retained, and the suffix indicative of a distance number is placed beneath it.

A rare suffix, the "bundle" element, is used with the katun and tun only to record anniversaries; that is to say, the completion of a number of tuns or katuns from some important date that is not a tun ending. An example of this is on Lintel 3, Piedras Negras. The Initial Series 9.15.18.3.13 is followed by the katun glyph with a "count" prefix and the bundle suffix. This date is precisely one katun later than a date prominent at Piedras Negras.

The suffix with three circles may be ornamental, or its meaning must be generalized; the other two suffixes are indicative of the way the periods are being used. There are somewhat similar distinctions in the Books of Chilam Balam.

The Maya language has a great number of numerical classifiers, each object or group of objects having its classifier. In English there are a few such numerical classifiers, e.g. head of cattle, loaves of bread, sheets of paper, but the system is with us vestigial. The Maya of Yucatán used *te* as a numerical classifier *inter alia* with years and months. In the hieroglyphic texts there is a small prefix which is sometimes placed between the numeral and the period or month glyph, but which never occurs with day signs. The fact that it sometimes appears as a suffix of head variants of numerals shows that it is connected with the number, not the period or month sign. It almost surely corresponds to *te*. This surmise is further strengthened by the absence of the prefix from day signs, since in spoken Maya the numbers with day names do not take this classifier. Its absence or presence seems to depend on the space available. It is most frequent with low coefficients, where its presence serves to prevent undue distortion of the accompanying glyph; it is almost unknown with high numbers.

The normal work of identification of glyphs has made some progress. Among new glyphs recognized is a rare head variant of the introductory sign to the distance number, there being a very fine example on Temple II, Copán. A section of the Dresden Codex has been found to treat of the burner period, prominent in the Books of Chilam Balam. Several new readings of dates have been made in addition to those published in various papers during the period covered by this report.

Mr. Thompson is now engaged in a comprehensive survey of Maya epigraphy. The first volume of this study should be completed during 1946.

6.7.

SYLVANUS G. MORLEY

Hieroglyphic Research

YB 45:207-208, 1946

Dr. Morley left Santa Fe for Yucatán October 28, 1945, by way of Mexico City. During his stay in the capital he visited the ruins of Tula, Hidalgo, which the younger Mexican archaeologists have conclusively demonstrated was the Toltec capital of Tula, and not San Juan Teotihuacán as originally held. The architectural

evidence shows a far closer connection between Tula and Chichén Itzá than between San Juan Teotihuacán and Chichén Itzá; indications are that Tula is pretty surely older than the Mexican Period at Chichén Itzá, and San Juan Teotihuacán is older than Tula.

The Hieroglyphic Dictionary was continued, Dr. Morley supervising and correcting the work of the dictionary draftsman, Sr. Isaac Esquiliano, who has been devoting his entire time to this project for the past four years. Most of the more than 400 known introducing glyphs and Glyphs G and F of the Initial Series, as well as Glyphs E, D, C, and X of the corresponding Supplementary Series, have been drawn, and it is hoped that all examples of the remaining two signs of the Supplementary Series Glyphs B and A, will be completed by the end of 1946, or early in 1947.

Some important discoveries of new epigraphic material by Mr. Giles G. Healey in the little-known region lying southwest of the Usumacinta River in Chiapas, Mexico, should be reported. At a new site, which he named Oxlahuntún, on the pilasters of a Palenque-type temple, he found the remains of an inscription in stucco, recording the Period Ending date 9.13.0.0.0, 8 Ahau 8 Uo; and at another new site named Lacanhá, near the Río Lacanhá, were found two inscribed stelae, one of which has the distinction of presenting three Initial Series, recording the following dates (Table 6.7.1):

Table 6.7.1. Calendrical Decipherments, Stelae, Lacanhá.

9.8.0.0.0	5 Ahau 3 Chen
9.6.(0).11.0	8 Ahau (18 Zac)
(9).8.12.11.(0)	8 (Ahau) (3 Kayab)

This condition is presented by only one other monument in the *Corpus Inscriptionum Mayarum* (Morley 1948; Altar 2 at Uxul, northern Petén, Guatemala, discovered by the Carnegie Institution in 1934).

Work on the reconstructed text of the Maya Chronicles by Professor Alfredo Barrera Vásquez and on the English translation of the Maya original by Barrera Vásquez and Dr. Morley has been completed, a draft of this manuscript is now ready for publication. Barrera Vásquez first made a translation of the reconstructed Maya text into Spanish, but it was found that for purposes of the English translation, a more faithful rendering of the original Maya could be achieved by completely by-passing the Spanish translation and putting the Maya directly into English. Indeed, it was found that the meaning of the original Maya could be more accurately rendered in English than in Spanish, because of the nondeclensional character of the Maya, which is probably closer in construction to English than to Spanish.

Last year Dr. Morley began to collect, classify, and list all known Maya inscriptions on stone, stucco, and wood, and a few engraved on jade, painted on pottery, or painted on the three known pre-Spanish hieroglyphic codices. The purpose of this project was to make a complete checklist of the *Corpus Inscriptionum Mayarum*; this is now ready for publication.

The manuscript of Dr. Morley's popular book entitled *The Ancient Maya* is now in course of publication, the English edition by the Stanford University Press, and the Spanish edition by El Fondo de Cultura Económica of Mexico City.

Dr. Morley's experience in translating the Maya chronicles in collaboration with Alfredo Barrera Vásquez had convinced him that for accuracy it would be necessary to be in closest contact with the translator of *The Ancient Maya*. He was particularly fortunate in obtaining for this the services of the Hon. Adrian Recinos. Mr. Recinos had previously made a distinguished Spanish translation of Dr. Morley's *Guide Book to the Ruins of Quiriguá*, which the Carnegie Institution published in homage to the Sociedad de Geografía e Historia de Guatemala. Mr. Recinos spent the three winter months with Dr. Morley in Mérida. The translation was completed and delivered to El Fondo de Cultura Económica early in March. Both editions are promised for early fall delivery.

Dr. Morley returned to his summer headquarters at Santa Fe, New Mexico, on May 24, to devote the summer and fall to reading proof on these two books.

6.8.

J. ERIC S. THOMPSON

Hieroglyphic Research

YB 45:208–209, 1946

During the past year Mr. Thompson has been largely engaged in writing the introductory volume to his survey of Maya hieroglyphic writing. This study has necessitated much research on specific problems of glyph formation.

The selection of some 2,000 individual glyphs for illustration and the checking of the artist's drawings with photographs have occupied much time but not been mere drudgery. Such work, in combination with general research on the subject, has revealed what may prove to be the closest approach to a key to Maya hiero-

glyphic writing which we are ever likely to have. The walls of Jericho will not fall at this blast, but the method may in time enable us to undermine the outlying fortifications in strategic locations.

This new attack, which is a development of those discussed in [Chapters 6.3 to 6.6], isolates synonyms in the main elements of glyphs and in their affixes. The system has to be used with some caution, for there is a danger of confusing synonyms with near synonyms. For instance, the various so-called ending signs are not true synonyms, but associated terms. Their meanings may be tentatively accepted as "completion of," "count of," "setting in order of," "expiration of," etc. On the other hand, we find a large number of elements which are always interchangeable. They apparently represent the same ideas and are true synonyms. The large group of symbols which represent water is a case in point, but the problem is not merely a question of identifying components of the group. A water element may often be added to a glyph to help in its identification. Thus, to a deity connected with rain may be added a water symbol as an attribute, more or less as St. Peter is painted or carved with his keys. Water is the precious object. Accordingly a water symbol could be used in that secondary sense.

Another large group of related symbols refer to the earth and the underworld. Maya deities have a disconcerting freedom of movement. Celestial deities make incursions into the realm of the underworld; terrestrial deities ascend to the skies. Symbols of the underworld serve as distinguishing characteristics of the gods of the nether regions, but they may also be attached to celestial gods to indicate a temporary abode underground. Thus, the sun god at night passes through the underworld on his journey from west to east. On such occasions he is decked with the symbols of the abode of the dead.

Clearly, if more symbols can be assigned to the groups already known, and new groups can be recognized, the problem of the glyphs will be much nearer solution.

One result of this work is to reduce the number of elements which can represent distinct ideas or words. This, of course, lessens the possibilities of much diversity in the still undeciphered parts of the texts. On the other hand, nearly 80 different affixes or pairs of affixes occur with a few of the most important main elements. Some of these combinations represent synonyms or near synonyms; but even allowing for synonymous affixes as yet unidentified, there must be a goodly residue with different meanings.

Maya hieroglyph writing cannot be attacked as an isolated problem. Religious beliefs, legends, associations of ideas, language structure, folkways, and related subjects are deeply involved. For a grasp of

them, it is necessary to delve deep in the mythology of the Maya and of their cultural coinheritors to the north. The phraseology of modern Maya prayers is also helpful in elucidating these matters. Collaboration with Ralph L. Roys in these and related problems has been highly rewarding.

6.9.

SYLVANUS G. MORLEY

Yucatán, Guatemala, Honduras

YB 46:187–188, 1947

On November 11, 1946, Dr. Morley reached Mexico City, where he remained for a week, most of the time in conference with the Hon. Adrian Recinos, former Ambassador of Guatemala to the United States, who translated his recent book, *The Ancient Maya*, into Spanish, and also with the staff of El Fondo de Cultura Económica, the publishers of the Spanish edition, which appeared in the late spring.

During the winter Dr. Morley was in Yucatán. In April he went to Guatemala, where he visited the ruins of Quiriguá, which, thanks to the care given them by the United Fruit Company he found to be in better condition, better bushed, kept in better trim, and the monuments better marked with descriptive signboards, than ever before.

Some fear has been expressed that the surface of the sandstone monuments at Quiriguá has been deteriorating because of exposure to the sun during the past 36 years. The high forest in which they were formerly buried in deepest shade was felled in 1911 by the School of American Research, to remove the danger of falling trees breaking the monuments, which had occurred in several cases previous to that time. A decade ago, Dr. Morley sprayed Stela K with an English preparation intended to protect sandstone buildings from deterioration, by sealing in the surface of the stone, thus preventing or retarding erosion. His examination of the Quiriguá monuments this spring convinced him that the spray had been most successful.

The local [United] Fruit Company officials were so co-operative as to carry out Dr. Morley's recommendation that the bushed area in the Great Plaza be extended. As cleared of trees many years ago by the School of American Research, only the western half of the Great Plaza had been exposed. This not only reduced

the apparent size of the plaza by half, but also failed to disclose its function as an amphitheater, a large three-sided enclosure surrounded by ascending tiers of stone seats. The Great Plaza now appears in its true character.

The new National Museum of Guatemala was not yet completely installed in April, but sufficient progress had been made in displaying the large amount of stone material, especially the Piedras Negras stelae and altars, to indicate that it would be one of the leading archaeological museums of America when finished.

The trip that Morley made to Copán in late March was his fifteenth. He found the ruins in a better state of conservation than ever before, owing to the extensive excavations, repairs, and conditioning operations of the Carnegie Institution during the past 12 years, and to the supervisory care given them by the government of Honduras.

A fragment of a new Initial Series was deciphered. This was discovered by Sr. Raul Pavón Abreú, Director of the Museum of Archaeology, History and Ethnology of Campeche, in the debris of Mound 7 at the western end of the Court of the Hieroglyphic Stairway. The inscription was very unusual in that its corresponding period glyphs faced to the right instead of to the left as is overwhelmingly the case in other inscriptions, and the corresponding coefficients were also on the right sides of their period glyphs instead of on their left sides. The reason for this inversion of the usual order was aesthetic, arising from the desire to have the hieroglyphs of this inscription face the central axis of the building on which they had originally been carved. Although the introducing glyph and the day and month signs are still missing, this whole Initial Series may be read as (9).8.8.16.10 (6 Oc 3 Kayab).

Before returning to Yucatán, Dr. Morley visited Tegucigalpa, where he called on Professor Angel Hernández, Minister of Public Instruction of Honduras, and congratulated him upon the splendid care the government of Honduras is taking of the ruins of Copán, perhaps the most spectacular archaeological site of the Maya Old Empire. Dr. Morley returned to Yucatán April 19 and to the United States at the end of May 1947.

Owing to the death of Dr. E. L. Hewett last December, the directorship of the School of American Research and the Museum of New Mexico, a joint institution at Santa Fe, became vacant. The managing boards of these two organizations had tendered this position to Dr. Morley, who has been associated with both organizations for many years. Dr. Bush gave Dr. Morley permission to accept the provisional directorship, to serve without salary so long as he should be connected with the Carnegie Institution of Washington, from which he retires July 1, 1949. With this understanding Dr.

Morley accepted the position offered him by Mr. Paul A. T. Walter, president of the managing board of the School of American Research, to take effect as of June 1, 1947, pending final approval at the annual meeting of the joint boards on August 23. It is hoped that an amalgamation of all the scientific organizations in Santa Fe, anthropological as well as historical, may be achieved under plans for reorganization already in course of being carried out.

6.10.

J. ERIC S. THOMPSON
Hieroglyphic Research

YB 46:188–189, 1947

During the past year Mr. Thompson has continued work on the introductory volume to his study of Maya hieroglyphic writing. This has entailed many unexpected forays into territories which, at the inception of the study, had been deemed sufficiently known to need no further exploration at this stage of the work, but which, it turned out, had to be probed in order to round out the introductory survey of the subject. Consequently, the first volume is not yet completed, but fuller information on specific problems compensates for the delay. For instance, as our knowledge concerning the subject of the hieroglyphic texts accompanying divinatory almanacs in the Maya codices appeared inadequate even for this initial stage, Mr. Thompson devoted much time to that matter, with the result that he now feels that he can get the general sense of most of those texts, and can offer specific translations of a number of the constantly recurring glyphs.

The problem of the hieroglyphic writing is not one that can be quickly solved. Progress in the past has been discouragingly slow, but now with each additional year of research, the speed increases slightly. During the past year a number of glyphs have been identified, and one or two additions have been made to the very small list of affixes of known meaning. Work on the illustrative material for the volume continues to be rewarding, and the linguistic side of the work has progressed, largely as a result of the very helpful co-operation of Mr. Ralph L. Roys. A point has now been reached at which the absence of full linguistic material on lowland languages and dialects related to Yucatec is making itself felt. It is not improbable that

good dictionaries of such Maya languages as Chol, Tzeltal, and Tzotzil would yield homonyms corresponding to apparent examples of rebus writing in the glyphs, for which homonyms are lacking in Yucatec. The situation is roughly what one might expect were one endeavoring to reconstruct Latin from modern Italian, but without access to full material in Spanish, Portuguese, and French. Members of the Summer Institute of Linguistics, who have much unpublished linguistic material from all lowland Maya groups except Chortí, have proffered their co-operation in this work, a generous offer which should prove most helpful.

One chapter and several appendixes of the introductory volume remain to be written, and, in addition, a very thorough revision will be necessary. The greater part of the glyphs to be used as illustrations have now been drawn, and it is hoped that the illustrative material will be completed by the end of the year.

Mr. Thompson was at Bonampak, Chiapas, in February and made drawings of such glyphs on the frescoes as were then visible. Among the sculptured dates recovered at that site are:

Table 6.10.1. Calendrical Decipherments, Bonampak.

Lintel 4	(9.8.9.15.11) or (9.11.2.10.11)	7 Chuen 4 Zotz
Stela 2	(9.17.5. 8. 9)	6 Muluc 17 Yaxkin
Stela 2	(9.17.18.15.18)	12 Etz'nab 1 Ceh
Stela 4	9.17.15. 0. 0	5 Ahau 3 Muan

There is also an Initial Series on the murals of Temple 1 which Morley has read as 9.13.0.3.4, 7 Kan 12 Zec. The lintels of this same temple have yielded two rather uncertain dates, and there is a badly weathered Initial Series of Katun 17 or 18 on the magnificent Stela 1. It is evident that Bonampak was a center of the hierarchic cult for a long period.

6.11.

J. ERIC S. THOMPSON

Hieroglyphic Research

YB 50:244-245, 1951

It had been Thompson's intention to study the Maya codices for the light they would throw on Maya life in the late period now engaging the attention of the Department. It became apparent, however, that in order

to achieve worthwhile results in that field it would be necessary first to make a dictionary of all Maya hieroglyphs other than the calendrical group. The need for such a dictionary has been noted over and over again in the past 40 years, but because of the magnitude of the task, no one has been willing to undertake it.

The noncalendrical glyphs of Copán, Palenque, Quiriguá, and part of Yaxchilán have been indexed. Photographs of texts or photostats of reliable drawings are cut up and the glyphs mounted on large cards. Similar glyphs are assigned to the same card with notations of two to four glyphs on each side of the glyph under study, and the associated date, for by noting the adjacent glyphs, clauses can be recognized.

Although this project is still in its early stages, and a full study must await the completion of the index, material of considerable importance is already coming to light which may supply information on the political organization of the Maya area and its linguistic divisions. Of interest in this connection are the many cases of glyphs which are frequent in one or more cities, but rarely or entirely absent in others. For instance, the bat glyph with *ben-ich* prefix occurs no less than 40 times at Copán, and there are doubtless many more examples in weathered texts at that site. It is also quite common at Quiriguá, but at Yaxchilán it is, somewhat rare, and at Piedras Negras, the glyphs of which have not yet been indexed, it is very rare or absent. At Palenque, with its long and well preserved inscriptions, it is not once found. Thus, as one passes westward the occurrence of this glyph diminishes from great abundance to complete absence. In contrast, other glyphs which are common at Palenque are absent in Copán. Yet some glyphs which are quite rare everywhere are represented by one or two examples in all the sites so far studied. Clauses, that is to say several glyphs found in association in several texts, seem to vary from city to city, for clauses which are very common at one site are not found in any other city so far studied.

It is too early to draw any conclusions from this material, but when the dictionary is finished, it should yield information on relations between one city and another, and may enable us to group various sites in sub-areas, perhaps in connection with studies of sculpture and architecture. Later, it should be possible to identify by glyphic correspondences the sites of the Central Area which influenced Yucatán, and perhaps identify the areas in which the surviving Maya codices were composed, although the poor condition of nearly all glyphic texts in the north Petén will handicap these lines of research. For example, one affix which is common in Codex Dresden would appear at this stage of the project to occur elsewhere only at Palenque. The inclusion of all Yucatecan sites as well

as the codical glyphs will lengthen this project very considerably, but at present it does not seem practicable to separate that material for treatment in a subsequent study. When the dictionary is completed, we shall know for the first time with what glyph every affix is used. Our previous studies lead us to believe that the affixes are the keys to the interpretation of the glyphs. Already much material on grammatical construction has come to light incidentally to the indexing of the glyphs.

6.12.

J. ERIC S. THOMPSON

Hieroglyphic Research

YB 52:287–288, 1953

The collecting of material for a catalogue of noncalendrical Maya hieroglyphs has continued [Chapter 6.11]. Having listed all legible glyphs from sites in the Usumacinta Valley, as well as from Copán, Quiriguá, and Palenque, Thompson is now starting on Petén texts. Unfortunately, Petén inscriptions are in considerably poorer condition than most of those already examined, with the result that much time is spent trying to identify weathered glyphs, and the rate of work is thereby retarded. Although texts are more numerous in the Petén than in the area so far covered by the study, the number of identifiable noncalendric glyphs will be markedly less, largely because of the present condition of the monuments, but partly because the percentage of noncalendric glyphs is lower.

The fact that Petén limestone is softer than the stone used in most sites already studied, together with the smaller proportion of texts sheltered from erosion by being placed inside buildings, will unfortunately distort the over-all picture of hieroglyphic writing which will finally emerge from this study. This situation has already been encountered at Cancuen, in the Upper Usumacinta Valley, for there the texts are so badly weathered that practically no glyphs could be catalogued.

In a previous report on this work, cited above, attention was drawn to the fact that some single glyphs and, most noticeably, nearly all glyphic clauses (glyphs up to seven or eight in number which occur together with slight variations in the order) are confined to an individual city. This condition has been found to apply to all other sites subsequently examined, and raises interesting questions. For example, the sudden adoption by most Maya cities of the uniform system of recording moons, as demonstrated by Teeple, points to unity in the Central Area at that point in the Classic period. Furthermore, the wide distribution of some rather rare glyphs, a number of which almost surely are those of gods, suggest that uniformity in religion was not confined to the worship of two or three of the most important deities, but extended to lesser members of the Maya pantheon. On the other hand, local glyphs and, even more so, local clauses seem to indicate a considerable degree of local independence.

Another factor is the borrowing of glyphs by one city from another. Occasionally, a single glyph, popular in the city of its presumed invention, was adopted by a neighboring center. One glyph which occurs a number of times at Piedras Negras appears once in a text at Yaxchilán, but nowhere else. Another, also of frequent occurrence at Piedras Negras, is found once at Palenque and once at El Cayo. The latter city, however, may have been a dependency of Piedras Negras, for it is less than 15 km distant. Texts at Bonampak confirm that city's close relation with Yaxchilán, previously deduced by Proskouriakoff from the art of the two cities. Such borrowings and connections may prove of considerable importance in assessing inter-city relations, especially as in most cases they can be dated closely.

There are now being drawn, under Thompson's supervision, all glyphic affixes so far listed. These are arranged to show at a glance what positions (left, right, above, or below the main element) each can occupy. The number of affixes so far isolated exceeds 200, although the tally includes a few forms which are probably variants of others. This listing is still incomplete, but it is of interest to note that the total in the codices is less than 100. The affixes, which roughly correspond to the articulation of the spoken language, are more generally distributed over the whole area than are complete glyphs, for few if any, are confined to a single city.

7.0. LINGUISTICS

7.1.

MANUEL J. ANDRADE

Linguistic Research in the Maya Field

YB 30:126–128, 1931

Our interest in the languages of the Maya peoples, aside from our concern with a number of linguistic problems involved in the study of Maya civilization, is but a manifestation of the desire which man has felt for centuries to understand the nature of language and its relations to many aspects of his experience, with which it seems to be so inseparably blended. The opinions of philosophers, logicians, psychologists and others on the relation between thought and language fill many a volume. Extensive chapters, articles and monographs on the origin of language can be counted by the score. But interest in psychological, social and historical problems involving linguistic phenomena is perhaps keener in our time than it has ever been. New lines of inquiry have developed, and questions which were considered settled have again been opened for discussion.

The criticism which has most frequently been leveled by writers on general questions pertaining to language is that their conclusions were based on too limited a number of types, chiefly on the languages of the

Indo-European and Semitic families. Aside from the fact that these were for some time the only languages which had received scholarly attention, there seems to have been a more or less manifest attitude that the languages of ancient literatures and those of modern cultured Europe were better specimens of genuine human speech than those of backward or savage races. A quotation from a primitive language was regarded by some as a piece of eccentricity. At present such an attitude would be as unjustifiable as that of a biologist who would infer general laws of life solely from a study of the commonly domesticated species. In his search for fundamental principles, neither the linguist nor the biologist can afford to neglect even the most exotic types.

From this point of view, the Maya languages are just as worthy of our attention as any others, but their connection with Middle American culture the highest accomplishment of aboriginal man in the New World, adds a particular interest to this field of research. It is to be expected that linguistic investigation will be helpful

in the solution of various problems of Maya culture, as it has been in the study of other civilizations. Moreover, owing to several fortunate circumstances, the Maya area offers special advantages to the linguist. We find 18 or 20 languages or groups of dialects in a continuous area, and one, the Huastec, which for many centuries has been isolated from the Maya region. This isolation is advantageous for the study of historical processes in the development of the various dialects from one ancient mother tongue from which we may present all of them have evolved. Thus upon finding, as we do find, elements which Huastec has in common with some dialects of the main group, we may safely infer that, either the elements themselves or the processes which produced them must have existed previous to the separation. Once the priority of certain elements has been established, we are in an advantageous position to trace various processes in those languages of the main group in which such old elements have disappeared or have been modified. On the other hand, we may profit by the fact that all but one of the Maya groups occupy one continuous area with hardly any natural barriers. Parallel to this geographical continuity we find, so far as we may judge from the scanty material available, a rather gradual linguistic diversification. In other words, between two distant and divergent languages we find a number of intermediate dialects whose mutual similarity is roughly proportionate to their geographical proximity. We are thus justified in expecting that the general absence of gaps may greatly facilitate historical reconstruction, as well as the study of mutual influences. However, for the study of these influences, even more favorable circumstances are offered by the presence of Spanish in this area. The Spanish language displaces the native idiom in the principal centers of Spanish culture, modifies it in the rural districts in proportion to their accessibility, and exerts, as one would expect, little or no significant influence on some isolated peoples. It is an excellent laboratory to observe the interaction of two totally different types of language in the midst of the continuous processes of cultural assimilation prevalent throughout this area.

Since linguistic affiliation coupled with geographical and cultural data has always revealed basic facts in the history of related peoples, one of the main objectives in our research should be to map out the genealogical tree, so to speak, of the Maya family, defining various groups of dialects, if their similarities and differences should so suggest, or we may trace the history of various elements or clusters of elements, if the facts do not justify any systematic grouping. The present classification of the Maya dialects is not reliable because it is based on observations from uncritical and scanty material for most of the dialects. Further-

more, what we have at present is simply a grouping without the proper weighing of the similarities and differences, with no attempt to trace significant processes. In order that a linguistic classification may properly serve historical interests, it is not sufficient merely to draw lines between languages which appear to have the greatest number of divergent elements. The similarities and the differences must be individually evaluated and accounted for so far as possible. Even in comparing vocabularies, for example, we all know that it is historically more significant to find that two different languages have a dozen words in common for parts of the body, than that they should have 100 identical words for objects and activities which one people could have transmitted to the other. Similar evaluations are necessary in comparing structural features, and it is on linguistic structure that our classification should rest primarily. It is obvious that a comparative study as outlined here may give us a different picture of the Maya linguistic area, and the consequent historical implications may throw light on the problems of Maya civilization, or raise new lines of inquiry.

Work on Maya linguistics with the modern method of approach was begun in February of 1930, under the auspices of the Department of Anthropology of the University of Chicago. The Carnegie Institution furnished informants and other generous aid while the work was done at the quarters of the Chichén Itzá Project in Yucatán. The writer worked in the states of Yucatán and Campeche till the latter part of June. Sufficient material was collected for an intensive study of the Maya spoken in that region. The months of July and August were spent in Tampico and in Chinampa, a Huastec village in the northern part of the state of Veracruz. A future field trip will be devoted to the closely related Huastec dialect spoken in various villages within the state of San Luis Potosí. The two Huastec dialects are locally referred to as Veracruzano and Potosíno, respectively. Abundant material should be collected on these two dialects due to the importance of Huastec in our comparative work, as suggested above.

In January of 1931, our work was extended to the Corozal district in northern British Honduras as a joint project of the Carnegie Institution and the Department of Anthropology of the University of Chicago. It was found that the Maya spoken there does not differ from that of Yucatán. One advantage derived from our visit to this region was our being able to study the speech of people from the interior of Quintana Roo, without the difficulties which an investigator would be likely to meet within that unfriendly territory. This was possible because of the continuous emigration of these people into the British colony.

From the Corozal district we passed to the south of the colony, and worked in San Antonio, a small village in the interior of the Toledo district. There we found the first variant of Yucatecan Maya which requires separate consideration. All the variations met with up to that time can be easily disposed of as mere colloquialisms, or as due to various degrees of Spanish influence. The founders of San Antonio came from San Luis, department of Petén, Guatemala, where, according to all reports, the same dialect is still spoken. They may, therefore, be considered as descendants of the Mopáns who, as the early historians tell us, were subjects of the Itzá ruler at Petén.

In the month of April we worked on Lacandon, a dialect spoken in one portion of the state of Chiapas, Mexico, and in scattered settlements in the surrounding country. This Maya variant proved to have a number of features in common with the Mopán dialect of San Antonio. Some of these features are not found in present Yucatecan Maya nor in the old Maya dictionaries and grammars. However, on the whole, Lacandon is closer to Yucatecan Maya than to Mopán.

Near the border line between Chiapas and Tabasco, the writer had an opportunity to study Tzeltal phonetics with two Bachajom Indians, from whom a vocabulary of more than 400 words and some grammatical material were collected. Additional Tzeltal material was obtained at the Department of Middle American Research of Tulane University, New Orleans, from a native of Chiapas.

By taking advantage of opportunities which presented themselves while traveling, similar material, though in smaller proportions, was recorded for three other members of the Maya family, namely, Kekchí, Palencano and Chuj, the latter also in New Orleans from a native of Guatemala.

The plan which seems advisable for future research in Maya linguistics is to complete an intensive study of Huastec, and then to proceed with a general survey of all the other dialects of the Maya family. This survey should include a careful study of the phonology, the collection of extensive vocabularies, sufficient material on grammar to obtain a general idea of the morphology, and some text material. This extensive study will offer suggestions as to the dialects on which further intensive work should be done. The intensive study should be applied to those languages which, from our general survey, may appear to be like points of departure from which a group of dialects may have evolved, or to those, if there be such, which may not naturally fit in any group. The main advantages of such a plan would seem to be a definite aim in each step, with a consequent economy of effort and, possibly, early results.

7.2.

MANUEL J. ANDRADE
Linguistic Investigations

YB 31:114–116, 1932

During the period under consideration no work was done in the field. It was thought advisable to devote this time to the study of the material collected in the two previous years, and to make preparations for future investigations. The usual routine of the morphological analysis of the hundreds of pages of texts and grammatical material, besides the various other procedures commonly employed in linguistic analysis, are the tasks which must be undertaken before a detailed account of the Maya language and its two closely related dialects, Mopán and Lacandon, can be given.

Part of the material recorded on dictaphone cylinders is now being analyzed with the aid of an oscillograph in order to obtain accurate measurements of certain tonal and duration factors which play an important part in the phonetic structure of the Maya language. Various technical difficulties had to be overcome before it was possible to obtain photographs of the sound waves recorded on the wax cylinders. Thanks to the expert collaboration of Mr. S. N. Treviño of the phonetics laboratory of the University of Chicago, the results are quite satisfactory. They will be the subject of a special article on the melodic patterns of Maya words.

Part of the preparations for future field work consists of the compilation of a linguistic questionnaire to be used in the study of all the languages and dialects of the Maya stock. A handicap with which students of comparative linguistics have frequently to contend is the omission of data in the material compared, which, in the course of the research, turn out to be the key to the solution of particular problems. Naturally, such gaps are more likely to occur when the information has been collected by different investigators. It may thus happen that it is not possible to trace the history, or map the distribution of a word connected with an important cultural fact because it is not found in the texts or vocabularies recorded in two or more of the languages compared. It seems possible to obviate such difficulties to a considerable extent by using a uniform set of questions for all the languages studied, in addition to the usual methods of collecting linguistic material. This questionnaire, to judge by the data thus far compiled, will consist of over 4,000 words comprising the names of the animals, plants, artifacts and other items of culture and physical environment which may be expected to be common to all the Maya-speaking

peoples. It will also include the current vocabulary essential in all human communication. Another portion of the questionnaire will be devoted to grammatical phenomena, the questions being designed to discover in each language the existence or absence of characteristic features observed in the related languages and dialects previously studied.

Other preparations are the selection and adaptation of apparatus to record and analyze speech sounds in the field. The collection of phonic material serves various important purposes. In the first place, it is desirable to have permanent phonographic records of the languages included in our project. The archaeologist and the student of material culture provide for future inquiry by storing in museums the products of the arts and industries of extinct civilizations as well as those of living cultures. The linguist, likewise, preserves his texts, a documentary evidence of the more important aspects of language, which facilitates future research by himself and others. However, his permanent records would be even more complete than those of the other students of culture were he able to file faithful reproductions of the phonic aspects of language. Until recently, the phonographic records which could be made in the field were very unsatisfactory for scientific purposes, and their permanency as material accessible to other investigators involves considerable expenditure of time and money. It is now possible to use in the field an electric apparatus to record speech on aluminum discs. Several copies can be made from one of these discs at a negligible cost, and it is claimed that each one of the aluminum copies can be played over two thousand times without any perceptible wearing. The Carnegie Institution has had such an apparatus constructed under specifications calculated to meet the requirements of our work. After a period of testing, it is now being improved under expert advice to provide against various difficulties encountered by the traveler in the less accessible parts of the Maya area. The apparatus reproduces, with more accuracy than has been possible heretofore, most of the physical aspects of sound which are of interest to the linguist. An archive of such records will doubtless be welcomed by students of aboriginal languages, not to mention others interested in problems of general linguistics.

Apart from its services for the above purposes, the writer believes that the use of such a machine will mark a distinct improvement in the technique of recording languages. As this is not the proper place to enumerate all its technical uses, it may suffice to mention one. A great deal of artificiality is introduced in the process of recording connected discourse in an unknown language. The informant must conform to the exigencies of the investigator by dictating at an unaccustomed slow speed, enunciating clearly, stop-

ping between the word groups of a given sentence if it happens to be long, frequently repeating some of the words before the sentence is completed, in order to facilitate phonetic observations, besides other disturbing factors familiar to all field workers. Many informants who can give valuable ethnologic information in their native tongue are not available to the investigator, because they can not adapt themselves to the unnatural conditions of dictation. If the informant is adaptable, the recorder may find it difficult to make various observations which may be of importance in some languages, as for example: the syntactic function performed by melodic aspects of the sentence, which may be evident only when speaking at a natural speed; word grouping- phonetic subordination, which may, occasionally decide whether a given morpheme is a proclitic or a prefix; and other points which may be negligible in some languages, but are always of interest to linguistic science in general. Such aspects of language can be more accurately and conveniently studied from the aluminum records mentioned above. It is true that the informant must at first become accustomed to speaking before a microphone, but this is rather simple in unsophisticated environments, especially if the native faces a group of his own people while recording. At least, such has been our experience in the use of the dictaphone in previous field work.

Another preparation which is now in progress is the selection of reliable instruments for the analysis of speech sounds, which can be adapted to field work. In recent times the physicist and the experimental phonetician have made considerable improvements in such mechanical devices, but practically all of these have been designed for the laboratory. Our task is to select the most essential of these modern inventions and to make such alterations as will facilitate their use where the conveniences of the laboratory are not available. Very little use of physical apparatus has been made in the past in the study of aboriginal languages. Most of the investigators have depended entirely on their auditory ability. Formerly this was due in part to the imperfection of the instruments that were at our disposal, and more recently, when such highly refined instruments as the oscillograph have been constructed, it is due, also, to the fact that they can not be used in the field. But besides these handicaps, there are also theoretical objections. Some investigators contend that speech sounds are essentially psychological facts, and hence observations on their physical aspects are irrelevant for linguistic purposes. In such extensive investigations as have been planned in our Maya linguistic project, it would not be advisable to neglect any aspect of the subject on theoretical considerations. The precise determination of the physical aspects of

speech in no way obstructs a psychological or purely linguistic interpretation. It may be argued further that, since it is the goal of every science to eliminate the personal equation to the greatest extent possible, it is desirable to avail ourselves of mechanical devices for the description of linguistic sounds, to the extent that the measurements thus obtained may be pertinent and reliable.

7.3.

MANUEL J. ANDRADE
Linguistics Investigations

YB 32:99–100, 1933

The first half of the period under consideration was devoted to the preparation of a description of the Maya language spoken in Yucatán and northern British Honduras. The completion of this work was postponed in order to concentrate on the analysis of the Huastec material collected in 1930, which had to be undertaken at this time in view of the fact that we intend to return to the Huastec region in the summer of 1933. Such preparatory work will enable us to enter the field with certain problems definitely formulated. It may thus be possible to concentrate our efforts on the collection of a sufficient amount of data to elucidate the most difficult aspects of this language.

So far as we may judge from the material in our possession, a thorough study of Huastec should throw considerable light on the history of the languages of the Maya stock. At present it is not safe to draw conclusions regarding the relation of Huastec to any other specific particular group of the Maya stock. Its structure is definitely Maya, but its vocabulary seems to contain many foreign elements, a study of which will doubtless indicate with what peoples this isolated member of the Maya family has been in more or less intimate contact. This will eventually necessitate a knowledge of such neighboring languages as Totonacan and Otomí. A study of Totonacan will be of particular interest, since it has been suspected by some writers, although on scanty evidence that it may be related to the Maya stock. However, the isolation of foreign elements in Huastec can not be undertaken with any degree of confidence until we can determine the phonetic and morphologic correspondences between this language and its cognates. Some words

which at first sight appear to be foreign may prove to be Maya. Such instances have already been observed in the limited comparative work which has been done.

In the summer and autumn of 1933, we shall for the first time use in the field the electrical apparatus designed for our future work in the Maya linguistic project. On that field trip we shall have an opportunity to try what may prove to be a more efficient technique of recording connected discourse than the usual method of dictation employed heretofore. Considerable time has been devoted to the perfection of the apparatus and to repeated experiments in conditions approximating those encountered in the field. It remains to be seen whether the equipment can be taken to the field without impairing some of its necessarily delicate mechanism.

7.4.

MANUEL J. ANDRADE
Linguistics Investigations

YB 33:103–105, 1934

In accordance with the plan outlined in a previous report [Chapter 7.3], the study of Huastec dialect spoken in the State of San Luis Potosí, Mexico, was undertaken during the summer and autumn of 1933. From the middle of August to the early part of December work was carried on in the village of Tancanhuitz and on two farms on the mountains that lie between Tancanhuitz and Tanlajas.

In Tancanhuitz, informants were chosen from the least assimilated of the Huastec residents and from those who came to the village to trade, some of whom could be persuaded to stay for three or four days.

The apparatus for recording speech, mentioned in a previous report, was given its first field trial on this trip. It proved to be an efficient instrument for field work, both with regard to its ruggedness and to its technical operation. The severe test it stood in transit to this region, and during more than 10 hours of exposure to the torrential rains of the cyclone that destroyed nearly half of the village of Tancanhuitz, dispels all doubts as to the possibility of recording speech by this means under ordinary field conditions. Another question which had been raised when we contemplated the use of this kind of apparatus in the field was whether the natives would speak freely in the presence

of a microphone and other devices equally mysterious to them. Our experience in this region is that they rather enjoy the performance, and that the inhibitions that some of us experience in such situations were not manifested even by informants who had never seen a common phonograph.

There were stated in a previous report [Chapter 7.2] the advantages it was expected would be derived from the use of this apparatus. It may now be in order to indicate the extent to which these were realized in the first trial, besides listing certain unanticipated advantages and disadvantages. It was found, as expected, that the number of individuals who can be utilized for the recording of text material, that is, connected discourse upon a subject of their own choice, is considerably greater when their speech is instantaneously recorded by means of this apparatus than by the usual process of recording by handwriting. This is so obvious that it hardly necessitated a test, were it not for the possibility that the presence of a strange apparatus might have been a disturbing factor. As indicated above, such a difficulty did not arise.

The possibility of recording speech instantaneously has also the practical value that advantage may be taken of the presence of an unusually good informant who may not be available to an investigator who records from dictation, for the simple reason that the native can not spare the time required by the latter process. On one occasion there were recorded three stories amounting to more than three thousand Huastec words from one individual who said he could spare only one hour. The actual recording of this amount of material must have been done within a limit of 36 minutes, since it filled six discs, and the time limit of one disc is six minutes.

One difficulty which had not been anticipated is that not all individuals can be used for the transcription of the records. Our procedure for this purpose consists in playing the record on a mechanical phonograph, reproducing one complete sentence at a time. The task of the native is to repeat what he hears. The investigator records his repetition phonetically, the object being to obtain a phonetic transcription of the record for the inter-linear translation and for other technical purposes which must be accomplished while in the field. The unexpected difficulty was that some individuals can not repeat the actual words reproduced by the phonographs, even for the records of their own recitations. It is much more natural for them to express the same or approximately the same sense in different words, result being a summary, or frequently an elaboration, of what they consider to be implicit in the original. In such cases we were not able to obtain the transcription with the help of the original speaker, but had to employ someone else. The errors in this pro-

cess are, of course, easily detected, for if a minor deviation is missed at the time that the informant repeats, it is a simple matter to check the transcription against the original record. However, individuals who can repeat properly are perhaps as easily found as those who can dictate satisfactorily for the procedure heretofore employed.

Although the original recitation is recorded instantaneously, and thereby one of the chief advantages is economy of time, the time required for the transcription of the record is generally longer than in recording directly from dictation. In our opinion this is a minor objection to the technique, if we consider the advantages above mentioned and the following.

By means of this technique we obtain a permanent record of some of the objective facts of the language investigated. At present such a record does not give us a complete reproduction of the original, but the accuracy of what it does reproduce can be determined by precise methods. Motion picture records are also incomplete reproductions of the original facts, but for the study of objects in motion their advantages over verbal or graphic records are quite obvious. A phonetic transcription of sound, as well as a description of objects in motion, contains no other basic facts than those which the investigator has observed, whereas a mechanical record may contain much which has escaped the attention of the original investigator, or which is irrelevant to his individual interests, but may be of value to others.

In December, as soon as the condition of the roads and bridges, consequent to the floods, permitted the transportation of our equipment out of the Huastec region, we went to Tampico, and sailed from that port for Yucatán to record, Maya-speech by means of our new device. Within two weeks we were able to fill both sides of 116 10-inch records, which was considered adequate for our purposes.

Thanks to facilities provided by the National Museum of Mexico and the Department of National Monuments, Professor Alfredo Barrera Vásquez, instructor in the Maya language at the University, spent two weeks in Tancanhuitz observing our methods of linguistic research. His knowledge of modern Maya, his native language, and his first-hand acquaintance with the flora and fauna of Yucatán were of valuable assistance in collecting Huastec terms pertaining to the latter subjects.

7.5.

MANUEL J. ANDRADE

Linguistics Investigations

YB 34:132–134, 1935

In January 1935 Dr. Andrade initiated a linguistic survey of the Republic of Guatemala. Lest it be not apparent how this undertaking fits into the general plan followed heretofore in his work on the language of the Maya stock, it may be desirable to refer briefly to the purpose which previous field trips were intended to serve.

The aim of the first field trip in 1930 under the auspices of the University of Chicago was to collect the data necessary to describe the aboriginal language of the Indian population of the peninsula of Yucatán, the language hereafter referred to as "Yucatecan Maya." Being aware of the historical interest connected with the study of this language, immediately after this first research, Dr. Andrade began his study of the Huastec language spoken present in the northern part of the state of Veracruz, and in the adjacent portion of the state of San Luis Potosí. The historical interests alluded to may roughly be specified as follows. Apart from the scientific interests which the description of a language can be expected to serve merely as a collection of facts, a comparative study of cognate languages not infrequently has thrown light on the history of the peoples who speak them. The circumstances that Huastec and Yucatecan Maya are evidently cognate, and that the peoples who speak them have not occupied contiguous geographical regions presumably for more than a millennium, are of the sort which have been particularly advantageous in other fields of historical inquiry. The possibility that such circumstances might be favorable has been realized in part and, although it is premature to make any pronouncement concerning further developments, it does not seem unlikely that future results may be illuminating. After this initial field research covering a period of seven months, further work on the Huastec language and on dialects closely related to Yucatecan Maya was conducted as a joint project of the Carnegie Institution of Washington and the University of Chicago. Up to this point the accomplishments may be thus summarized: 1. We have material for a detailed description of Yucatecan Maya and Huastec, two divergent members of the Maya linguistic family. 2. This material serves as a convenient yardstick, so to speak, to estimate the structural and phonetic divergences of any language of the Maya family which may be the object of future research. 3. The Huastec material is intended

to serve as a point of reference to determine under favorable conditions the relative antiquity of the linguistic facts observable in the present stage of the languages of this family.

This third particular has an obvious bearing on historical interests, while the second may, or may not have a direct bearing on such interests, depending on the nature of the facts which future research may reveal. The degree of linguistic divergence among geographically contiguous or remote languages can be indicative of historical events. So far as one may venture a conjecture grounded on the available data, it seems that, with few exceptions, linguistic divergences and geographical proximity or remoteness are roughly proportionate in the Maya area. If future research proves that such is actually the case, the facts may justify at least one historical hypothesis, namely, that it is probable that the peoples who speak the various contiguous and slightly divergent languages and dialects have occupied the same or similar geographical positions with respect to one another for a period of time proportionate to two factors: a. degree of divergence, and b. rate of divergence, that is to say, rapid or slow change. The latter factor is of difficult determination at the present stage of our knowledge of linguistic change, but under favorable circumstances and within wide ranges some possibilities may receive more support than others.

With this initial work, as a provisional basis, further steps in the Maya linguistic project follow the plan outlined in [Chapter 7.1], wherein it was stated that the plan which seems advisable for future research in Maya linguistics is to complete an intensive study of Huastec, and then to proceed with a general survey of all the other dialects of the Maya family. This survey should include a careful study of the phonology, a collection of extensive vocabularies, sufficient material on grammar to obtain a general idea of the morphology, and some text material. This extensive study will offer suggestions as to the dialects on which further, intensive work should be done. The intensive study should be applied to those languages which, from our general survey, may appear to be like points of departure from which a group of dialects may have evolved, or to those if there be such, which may not naturally fit into any group. Thus, Dr. Andrade's field trip to Guatemala during the period covered by this report conforms with the original plan, although the procedure to which we shall presently refer was suggested by the conditions disclosed in this last field work.

The conditions referred to are as follows. Several Quiché informants from the neighborhood of Chichicastenango asserted that the speech of certain other parts of the Department of Quiché was different from

theirs. The differences were characterized (as untutored individuals would generally be expected to do) on the basis of mutual intelligibility, or merely as "different" in various degrees. Thus, they would say, "We can not understand the people of X" or "The people of Y speak in a manner quite different from ours," or "We can communicate with the people of Z, but their speech is peculiar." Now, according to all the linguistic maps available, the people of X, Y and Z are supposed to speak Quiché. There is nothing unusual about this, of course, if we consider that a linguistic map of Europe may represent the Italian peninsula and some of the adjacent and more distant islands as having Italian for their common language, whereas a detailed map might show eight dialectal divisions of Italian and 16 subdivisions of these eight divisions. However, in view of the fact that the speech of the area labeled "Quiché" on the maps is not uniform and that the Quiché of some sections is easily intelligible to the Cakchiquel of certain sections but not to others, it would not be advisable to rely on the linguistic maps without examining the situation more closely. Specific instances are exemplified in the linguistic relations of Chichicastenango, Tecpán and Sololá. The peoples of the last two places are supposed to speak Cakchiquel, but, according to all the natives questioned, they can not understand each other's dialects. Whereas the natives of Chichicastenango, who are supposed to speak Quiché, can converse with the natives of Tecpán as easily or, according to some, more easily than with other Quiché peoples. The report that the Quiché of Chichicastenango can communicate in their own dialect with the Cakchiquel of Tecpán was submitted to a test during Dr. Andrade's stay in Chichicastenango, and its accuracy was corroborated in a rather conclusive manner. To what extent all the reports concerning differences and similarities of speech are true, and whether or not such situations obtain throughout the Republic of Guatemala are the queries which will guide our linguistic research in the immediate future.

The procedure will be as follows: 1. In a given community, A, a number of electric records of free speech will be made, in addition to and as a part of the material referred to in the above quotation of our original plan. As usual, the records are translated as accurately as possible with the aid of individuals of the community A. 2. As many individuals of community A are questioned as to the speech of neighboring communities. If their answers agree concerning the absence of dialectal differences in community B, but there is complete or partial agreement as to the dialectal differences in community C, we proceed to work in C and postpone our investigation in B, or devote sufficient time to it to verify the reports, provided, however, that favorable conditions obtain, such as, for example, the

location of B on the road to C. 3. In community C the natives listen to the reproduction of the speech recorded in A and if they claim to understand it, their translation is compared with that given by the natives of A. In brief, objective data are thus obtained as evidence that the people of C do or do not understand the speech of A, or understand it partially. If they do not understand it, community C is the immediate locus of our further research.

Within the confines of this report, it is not feasible to enumerate the technical advantages which are expected to result from the employment of this procedure in our survey, and the opportunities for the disclosure of information pertinent to the chief goal of the Maya linguistic project. To cite one particular, the survey is expected to give us what we may provisionally call a map of mutual intelligibility. Among the various uses of such a map, it may be pointed out that it can be a valuable aid to the ethnologist, besides providing organized material for a reliable genetic classification of the extant dialects of the linguistic family under consideration. In other words, it can be both an instrument of research and a useful by-product.

In this first field work in Guatemala, Dr. Andrade had opportunity to take notes on the Quiché dialects of Chichicastenango and Totonicapán, on the Jacalteco dialect of Santa Eulalia, and on the Mam of the neighborhood of San Juan Ostuncalco. The chief aim of the trip was to become acquainted with the linguistic situation in Guatemala, although the material collected in Chichicastenango may serve as the first sampling in the survey.

7.6.

MANUEL J. ANDRADE

Linguistic Investigations

YB 35:134-136, 1936

In the winter of 1936 the linguistic survey of Guatemala included the villages surrounding Lake Atitlán, and the Pokomam-speaking population of Mixco, Chinautla, and Palín in the vicinity of Guatemala City. Most of the field trip was devoted to the localities around Lake Atitlán.

According to the linguistic maps available, three languages are spoken on the shores of Lake Atitlán: Cakchiquel, Tzutujil, and Quiché. The results of the

survey, however, show that no Quiché is spoken in any of the villages surveyed. The localities where our material was collected are Panajachel, Santa Catarina Palopó, San Antonio Palopó, San Lucas Toliman, Cerro de Oro, Santiago Atitlán, San Pedro, San Juan, San Pablo, San Marcos, and Santa Cruz. The differences of speech among these localities are roughly proportionate to their geographical proximity. Cerro de Oro constitutes a special exception due to the fact that it was founded about two generations ago by Cakchiquel-speaking people who came from Patzicia. There is also a rather sharp distinction between San Antonio Palopó, where one language is definitely Cakchiquel, and San Lucas Toliman, where one of the variants classified as Tzutujil is spoken. On the other hand, it is difficult to decide whether the speech of San Pablo on the northwestern shore is Cakchiquel or Tzutujil. With respect to this village, we cannot say at present whether we are dealing with a Cakchiquel dialect which has been deeply modified by the influence of Tzutujil, whether it is a Tzutujil dialect modified by Cakchiquel, or whether its speech represents an older language or dialect spoken previous to the differentiation between Tzutujil and Cakchiquel. A careful analysis of the material collected and additional data to be collected in the future may or may not decide which of these three hypotheses is tenable, but for the present we can not venture even a conjecture. What can confidently be asserted about the localities surveyed is that the speech of any one of them differs from that of any other to the extent that the differences are evident even in data which can be collected two or three hours. And it should be noted that we do not refer merely differences of pronunciation. No two of the villages cited have identical series of personal pronouns, for example, and in two contiguous localities the names of such common animals as cat and pig are of different provenance in some instances. In Panajachel, Santa Catarina, and San Antonio, three contiguous localities on the northeastern shore, the word for "fish" has nothing in common with the word used in the rest of the places sited, nor is it conceivable in the light of our present knowledge of the Maya languages that the two words can be cognate.

In so far as diversity of speech is concerned, a similar situation was disclosed in the three Pokomam localities investigated. In the town of Mixco itself very few individuals speak Pokomam, Spanish having largely replaced aboriginal speech. That is not the case in Chinautla. There are differences between the Pokomam of these two localities, but they are negligible as compared with the Pokomam of Palin. Here we find again the general correlation between speech similarities and geographical proximity which is true for most of the places thus far covered by our survey of

Guatemala. The Pokomam of Palin differs less from Mam than that of Chinautla Mixco. Whether the speech of the last two localities is similar to that of the Cakchiquel villages near them we do not know. Those Cakchiquel villages have not been investigated, and, in view of the prevalence of diversity within the Cakchiquel region around Lake Atitlán, we can not venture to draw any conclusion on the basis of the material available.

The situation portrayed here is in agreement with that observable at the border line between Quiché and Cakchiquel, as stated in our report for 1934-35. The local diversities suggest the need of detailed research before names of the languages on our linguistic maps can have any precise significance. A comparative study of the languages of Guatemala can not be guided by the maps. An investigator who decides to write a description of Cakchiquel, for example, can not limit his research to any particular locality within the area assigned to this language on the maps. If he does so, he can not claim that he is describing the Cakchiquel language. Some of the facts he presents may be verifiable for the whole Cakchiquel region it is true, but many others may be observable only in the locality he studied.

In still another respect one can not be guided by the linguistic maps of Guatemala. For obvious reasons, historical facts have been taken into account in the delimitation of the various languages. The conventional distinction between languages and dialects is as misleading here as it has always been in Europe to anyone who is not acquainted with the linguistic facts. For example, Spanish and Portuguese are considered as being two languages, and not two related dialects, while Sicilian occupies the rank of dialect with respect to standard Italian. On the basis of purely linguistic criteria, either Spanish and Portuguese are two Romance dialects or Sicilia should be classified as a language. The linguistic atlases of Europe based on detailed research reveal the arbitrariness of dialectal delimitations conceived in the past. Cultural and political considerations are irrelevant in the proper application of the terms "language" and "dialect." With regard to Guatemala, it is quite evident that if Tzutujil and Cakchiquel are regarded as two languages, there may be many more languages in the Maya area than our traditional delimitations reveal. It is quite probable that the Maya of San Antonio, British Honduras, differs more from the of the northern portion of that colony than Tzutujil does from Cakchiquel. Also, according to several informants in Chinautla, the Pokomam of that village differs less from Pokonchi than it does from the Pokomam of Palin. With regard to other matters, the reports of the untutored native are not always accurate, but comparisons based on the possibility of understanding the speech of neighboring

localities are on the whole quite in conformity with the facts. We give considerable credence, therefore, to the report that Pokonchí and Pokomam are not different languages.

The historical implications of the gradual linguistic diversity observed in Guatemala are rather clear. They definitely suggest that the present distribution of languages and dialects is of long standing. That inference is equally valid whether we assume a long process of mutual influence upon languages which were at one time more divergent than they are now, whether we assume that the languages diverged from one common source at approximately the same places where they are spoken at present. In this respect, the apparently sharp differentiation of Mam from some of the contiguous languages must be significant, although for the present we can not venture to say what it indicates.

7.7.

MANUEL J. ANDRADE

Linguistic Research

YB 36:148, 1937

The chief aim in the linguistic research conducted in Guatemala during the first quarter of 1937 was to collect sufficient text material for a detailed description of the Mam language, the importance of which in a study of the history of the Maya linguistic stock has been pointed out in previous reports.

With the aid of the recording apparatus recently constructed for this purpose, it was possible to collect in one month texts conservatively estimated at more than 300,000 Mam words. This material is contained in 300 double-face aluminum disks, and consists of spontaneous discourse, mainly dialogues, representing the speech of informants from various parts of the Mam area, including the Tacaná region, wherein the speech is known to be like that of the Mam people of Chiapas, Mexico.

Considering that he was in possession of a rather unusual amount of text material to work out the description of Mam, Dr. Andrade moved his headquarters from the Department of San Marcos to that of Huehuetenango in order to continue the survey of the languages of Guatemala undertaken in 1935. He worked on the speech of Aguacatán, listed by Stoll as

one of the languages of the Maya family. Additional information was collected also on the speech of the villages north of Huehuetenango, a region concerning which Stoll's linguistic map of Guatemala is most inexact. The villages referred to are Solomá, Santa Eulalia, Barillas, San Miguel, Jacaltenango, San Juan, and others in their vicinity, where Solomec, Jacalteco, and Chuj are spoken, according to Stoll.

The language called by Stoll and others Aguacateca is spoken only in a small village named Aguacatán. Dr. Andrade has not studied the material collected sufficiently to pronounce on the classification of this speech, but it appears to be much like Mam, although it is totally unintelligible to a Mam. According to the native Aguacatec and their neighbors, the speech of Aguacatán is understood by no one outside their village. A similar condition exists, according to all reports, in Sipacapa, a village surrounded by Mam-speaking peoples. The speech of Sipacapa, however, has not been listed as a separate language, or even as a dialect. Of course, intelligibility cannot be the basis for determining whether or not it is justifiable to regard the speech of a locality as a separate language. If future research shows that the speech of Sipacapa is a Mam variant, that village constitutes a conspicuous exception in the Mam area, where local variants do not diverge to the point of being totally unintelligible in ordinary discourse.

7.8.

NORMAN A. McQUOWN

Linguistic Research

YB 46:193-195, 1947

Mr. McQuown undertook the continuation of the work on the Maya Linguistic Project on September 1, 1946. He devoted the first month to familiarizing himself with and making an inventory of the Maya materials collected by the late Dr. Manuel J. Andrade and elaborated by Abraham M. Halpern during the relatively brief period which he was able to devote to this task [Chapters 1.30 and 1.31]. A program of work for the year 1947 was sketched out. In this, Mr. McQuown was guided by the interim report on the state of the project prepared by Mr. Halpern in July 1946, before he left for duty with General MacArthur in Japan. The more important parts of this report are outlined here:

- A. The basic aims of the work on the Maya languages:
1. The glaring deficiencies in the amount and quality of available primary source material should be corrected.
 2. A certain amount of the material collected should be synthesized in the form of grammatical sketches.
 3. The material should be examined from the point of view of comparative linguistics, so that ultimately the general lines of development of the Maya language family could be laid down.
 4. In the course of the achievement of the first three objectives, special problems of particular interest, either for general linguistics or for workers in the related fields of Maya archaeology and ethnology, would at least be indicated, if not worked out exhaustively.
- B. The general goal of the Maya linguistic research: The research was designed not so much to produce the last word on all problems of Maya linguistics as to complete basic research and arrive at basic conclusions of a sort that would put Maya linguistic research on its feet scientifically.
- C. Necessity of the work: That this research was necessary is beyond all possibility of question. The available materials of a descriptive nature were thoroughly antiquated. In the field of comparative Maya linguistics, deficiencies in the descriptive data made it impossible to arrive at conclusions based on anything more than the most superficial kind of inspection.
- D. Status of the project at present: Of the objectives mentioned above (A), Andrade went a long way toward realizing the first, the compilation of material. With regard to the second objective, he had, before his death, almost arrived at the completion of a grammar of Yucatecan Maya, but had put nothing on paper with regard to the other languages. For all the languages except Yucatec, the material is in the form of raw field data. With regard to the third objective, Andrade accomplished little or nothing. With regard to the fourth, he called attention to the possibilities inherent in the application of dialect-geography techniques to at least the Guatemalan languages and had begun to collect materials on which such a study could be based, but he had not initiated the work of processing the materials toward this end.
- E. Materials collected by Andrade:
1. Huastec: a rather extensive body of text materials, vocabulary and paradigmatic material for the Potosíno dialect, and a relatively small body of material of the Veracruz dialect.
 2. Yucatán Guatemala languages: an extensive amount of material on Yucatec, Mam, and the Panajachel dialect of Cakchiquel; a moderately extensive amount of material on Quiché and Kekchí; small bodies of material on Pokomam, various Tzutujil and Cakchiquel dialects, Aguacatec, and Jacaltec.
 3. Chiapas languages: very small amounts of material.

- F. Condition of the materials: Linguistic materials in the form of raw field notes are rarely susceptible to immediate exploitation by anyone other than the original collector. The process of collection of field material is such that every investigator is forced to adopt certain expedients which depart in one way or another from standardized practice, and an investigator rarely leaves a complete record of such departures and the reasons for them. With Andrade's death, a great deal that he knew but had not written down was lost irrevocably.

There are certain inconsistencies in recording. In many cases one cannot be sure which of two or three variant recordings represents the norm for any given word and which are variations from the norm. In some cases, one can decide on the basis of the notes that the balance of likelihood is in favor of one variation rather than another. An unsolved phonetic question of major importance in all the languages is the presence or absence of phonemic length and accent. In most cases of variant recordings, different interpretations are possible, but if one operates entirely from Andrade's field notes, it is difficult, perhaps impossible, to decide which interpretation best fits the facts.

These difficulties exist if one relies exclusively on the field notes as they stand or on the phonograph records, which unfortunately fail one on many of these points. A short period of field work, in which an investigator would have the opportunity of observing the phonetics at first hand, would, however, be sufficient to settle all the doubtful points and would even enable the investigator to make use of untranscribed, phonograph records.

It is now customary among linguistic field workers to supplement text, material by extensive collections of paradigmatic material relevant to the analysis of the texts. Andrade's technique was somewhat different from this. His questions were standardized for all languages in order to facilitate comparison on certain specific points of grammatical structure. This material is extremely useful, but needs some supplementation.

- G. Recommendations for further work of compilation:
1. The investigator should have the opportunity to familiarize himself with the phonetics of the various languages through direct field work.
 2. The investigator should have the opportunity to collect further paradigmatic material.
 3. The investigator should devote some time to the collection of folkloristic texts where obtainable.
- H. Recommendations for further descriptive and comparative work:
1. The Yucatec grammar is already well handled, so little or no further work need be done there.
 2. A grammar of the Potosíno dialect of Huastec should be an immediate task.
 3. Concentration on Mam in the Yucatán-Guatemala area is recommended, since the Mam materials are among the most extensive in the collection, and one can expect to find certain archaic features

preserved in Mam which have been lost in some of the other languages.

4. If time permits, one of the Chiapas languages should be investigated intensively and the others merely surveyed.
5. The dialect study of the Cakchiquel and Tzutujil area should be carried out, but should be treated as a pilot study in which the objective would be to formulate the types of problems that arise and to indicate the methods which are applicable.
6. The elucidation of the internal relationships within the Maya family and the reconstruction of Primitive Maya should be prime objectives.
7. It is very probable that in the course of reconstructing Primitive Maya, the scholar engaged on this task will find leads indicating the direction in which external relationships must be sought.

Mr. McQuown accordingly devoted the following two months to getting acquainted with Andrade's phonetically and phonographically recorded Potosí Huastec materials, and with the dictionary materials compiled by Halpern from the raw data. It soon became apparent that a small number of fairly important phonological problems and a large number of morphological questions could not be solved on the basis of the available material. Accordingly, a field trip to Las Armas, San Luis Potosí, Mexico, was undertaken; nine days were devoted to the collection of a vocabulary of about 2,000 items, a considerable amount of paradigmatic material related to the verb, and a couple of texts. With this material, together with general notions obtained from the survey of the previously collected material, it was possible to work out the sound system and a beginning was made toward working out the morphology and syntax. The elaboration of the materials gathered on this field trip was continued during the first six months of 1947, when the major portion of Mr. McQuown's time was devoted to teaching linguistics in the Department of Anthropology at the University of Chicago. A start was made on the compilation of a Spanish-keyed comparative Maya vocabulary, from which will be drawn the cognate material to be used in working out the sound-correspondence matrix for the various languages of the family, and for reconstructing Proto-Maya.

Mr. S. L. Bradshaw, commissioned by the Institution to prepare the manuscript of Andrade's Yucatec grammar for the printer, completed his work and submitted the manuscript early in 1947.

It is hoped that by 1950, the general outlines of a comparative Maya grammar may be laid down.

7.9.

NORMAN A. McQUOWN

Linguistic Research

YB 47:221, 1948

Dr. McQuown spent the time from July 15 to December 15, 1947 on a field trip to Tancanhuitz, San Luis, Potosí, Mexico. The purpose of this trip was to gather material for the completion of the descriptive phase of the work on Huastec. A short field trip had previously been undertaken (November-December 1946), and the material gathered at that time was used as a basis for a phonemic analysis, which in turn made it possible critically to examine the Huastec materials collected by Andrade [Chapter 7.8]. This examination made it apparent that the transcription of the recorded text materials would have to be checked and completed in those aspects (stress, vowel length, glottal stop) in which it fell short, and that further paradigmatic material (without which it would be difficult or impossible to work out the grammar) would have to be obtained, working with an informant in the field.

During the four months actually spent in the field, the following was accomplished: 1. A Huastec grammar and dictionary file of approximately 10,000 entries was collected; 2. A Huastec grammar, in its essentials, was worked out; 3. The transcription and translation of the Potosí Huastec texts recorded (phonographically or phonetically in notebook) by Andrade were checked and completed; 4. A half-dozen new texts (of ethnographic or folkloristic interest) were taken down; and, 5. A short vocabulary of the Veracruz dialect was obtained.

The Potosí materials alone will constitute an adequate basis for comparison with the other Maya languages. The Veracruz materials (Andrade's and McQuown's) may be worked up in the form of notes to the Potosí materials, or may be used as a basis for eventual further study, pending the collection of additional data from Veracruz.

The major part of Dr. McQuown's time from January to June 1948 was taken up with the teaching of linguistics in the Department of Anthropology at the University of Chicago, the remainder with the elaboration of the Huastec materials.

In process, and near completion, is a Spanish-Huastec dictionary file, based on the collected materials. This will be incorporated into the Spanish-keyed comparative Maya vocabulary, together with materials from other Maya languages.

Now completed, in card file and in notebook, are:

1. A descriptive grammar of Huastec; 2. A collection of

40 Huastec texts, completely re-transcribed and re-translated from the phonetically and phonographically recorded materials; and, 3. A dictionary file (Huastec-Spanish) covering these materials. This concludes the descriptive phase of the Huastec work.

7.10.

NORMAN McQUOWN

Linguistic Research

YB 48:236–239, 1949

Dr. McQuown's primary purpose in his trip to Guatemala in the summer and autumn of 1948 was to educate himself with respect to the phonemics and a good part of the morphology and syntax of the Mam language. Among his secondary purposes were: to familiarize himself with the phonemics of the other Guatemalan, languages in which Andrade made phonograph recordings (Quiché, Kanjobal, Kekchí); to do the phonemics of Cakchiquel, for which Andrade gathered extensive written texts (transcribed by Juan Rosales); to take a look at Xinca, in order to get an outside check on Maya-non-Maya cultural contacts; and to make arrangements (both in Guatemala and in Mexico) for utilizing, so far as possible, the Maya materials already collected, or in process of being collected, by missionaries working with these languages in the field, and to ensure their collaboration and aid in further work on the languages of the family. A certain measure of success was attained in all these undertakings.

Five months were spent in Guatemala and Mexico, and the items listed were accomplished:

1. Three and a half months were spent in Guatemala City, working on Mam, with an informant generously furnished by the Instituto Indígenista; and one week was spent with Mr. and Mrs. H. D. Peck, at Txol Be, San Juan Ostuncalco:
 - a. A Mam grammar and dictionary file of some 7500 entries was accumulated;
 - b. The phonemics and a considerable portion of the grammar of Mam was worked out;
 - c. Some 10 Mam texts were collected incidentally, in the process of teaching the informant to write with a phonemic alphabet;
 - d. The Instituto Indígenista was provided with a Mam alphabet;

- e. Mutual orientation sessions were held with the Pecks, in which the problems of Mam phonemics and grammar were discussed;
 - f. Arrangements were made with the Pecks, with the informant, and indirectly with Mr. and Mrs. Edward Sywulka, to collaborate in the preparation of a Mam dictionary;
 - g. Arrangements were made with the Pecks to complete the transcription and translation of Andrade's 300 Mam recordings (all material to be phonemically transcribed according to a system worked out on this trip); they have already made great progress, and should be able to complete the work in another year;
 - h. Arrangements have been made with Mr. Edward Sywulka to have access to his master's dissertation, *A Morphology of the Mam Language*, recently completed at the University of Oklahoma. The continued collaboration of Mr. Sywulka and of the Pecks in working out unsolved problems of Mam grammar will probably make further actual field work on Dr. McQuown's part unnecessary for completing the descriptive phase of the work on Mam.
2. Two weeks were spent in becoming familiar with the phonemics of the Quiché, Kanjobal (Jacalteco), and Kekchí languages, in each of which Andrade made a fair number of recordings (55, 37, and 23, respectively).
 - a. Two days were spent in Chichicastenango, working on Quiché, with three informants from Chichicastenango and one from Totonicapán. A vocabulary of 1,000 items was taken and a tentative sketch of the phonemics was worked out (subsequent work in the Instituto Indígenista with another informant from Totonicapán verified the results of the first sketch and, in addition, established beyond question the phonemic status of the short and long vowels). Brief checking was done on a preliminary transcription of the Quiché recorded materials prepared by Andrade (the newly discovered feature of vowel length will make re-transcription of all materials necessary). The Instituto Indígenista was provided with a Quiché alphabet; on the previous trip to visit the Pecks, arrangements were also made with Mr. and Mrs. Stanley Wick, working with the Quiché of San Cristóbal, for future collaboration in all aspects of the work on Quiché;
 - b. Two days were spent in Huehuetenango, working on Kanjobal Andrade's Jacalteco) of Santa Eulalia, with the informant of Mr. and Mrs. Newberry Cox, at present in San Miguel Acatán. A vocabulary of some 1,500 items, a text, and some paradigmatic materials were recorded; a tentative sketch of the phonemics was worked out; vowel length was not found, but subsequent work with other Guatemalan Maya languages (Quiché, Cakchiquel, and Kekchí) which have it makes a recheck desirable (although there is

- evidence that some of the Chiapas languages do not have phonemic vowel length and that Kanjobal may belong with them rather than with the other languages in Guatemala). The collaboration of the Coxes will make this recheck possible without further fieldwork; they can also be counted on for help in the transcription and translation of that part of Andrade's recorded material which is as yet unworked. The Instituto Indígenista was provided with a Kanjobal alphabet;
- c. Two days were spent in San Juan Chamelco, working on Kekchí, with the informant of Mr. and Mrs. William Sedat. A vocabulary of some 1,000 items was recorded; a tentative sketch of the phonemics was worked out (phonemic vowel length was definitely established). The collaboration, of the Sedats can be counted on in the future for the working out of the grammar, and the transcription and translation of that part of Andrade's materials which is as yet unworked. The rechecking of the already transcribed materials will in the case of the Kekchí involve a minimum of effort, since Andrade indicated in these materials a fair portion of the long vowels. The Instituto Indígenista was provided with a Kekchí alphabet.
 3. One week was spent on the phonemics of Cakchiquel; one day was spent in San Pedro Yepocapa, working on the local dialect. A vocabulary of some 750 items was recorded, and a beginning was made toward teaching the informant to write; a tentative phonemic sketch was worked out. Subsequently, three days were spent in Panajachel, working on a slightly divergent dialect, with five informants. A vocabulary of some 1,300 items was recorded; a tentative phonemic sketch was worked out (subsequent work in the Instituto Indígenista with an informant from Comalapa, and in Mexico with Juan Rosales of Panajachel, confirmed the sketch, and established both short and long vowels as phonemic). The Instituto Indígenista was provided with a Cakchiquel alphabet. Juan Rosales, in view of the establishment of vowel length as phonemic, will have to recheck the texts written by him, indicating long vowels where they occur.
 4. The extra-familial check was accomplished in two days, which were spent in Chiquimulilla, working on Xinca, with an informant from Santiago and one from San Sebastián. A vocabulary of some 750 items was recorded and a tentative sketch of the phonemics was worked out. Instituto Indígenista was provided with Xinca alphabet. Subsequent inspection of the Xinca vocabulary showed some dozen loan words, some from Nahuatl languages, some from Maya; consideration of the Maya loans ("bean," "mat," "custard apple," "witch doctor," "ladino") shows that they were borrowed from Mam or from Kanjobal (or from one of the Chiapas languages), indicating a previous more northerly location for the Xinca; comparison of "bean" (from Maya) with "corn" (either a loan from Lenca or a loan into both Xinca and Lenca from a third language) would indicate that "bean" was acquired considerably later than "corn," and was introduced to the Xinca (and apparently to the Lenca and other Middle American groups) by the Maya. These "explanations" are only conjectures, of course, but they indicate how extremely fruitful further work might be. Xinca is rapidly going out; someone should do a thorough study before it becomes extinct.
 5. The fifth purpose was accomplished, by and large, in the personal meetings with individual missionaries. Collaboration has been secured with the Pecks and the Sywulkas for Mam; with the Coxes for Kanjobal; with the Wicks for Quiché, with the Oughtens for Ixil; with the Sedats for Kekchí; with Antonio Goubaud and the workers of the Instituto Indígenista for Cakchiquel, Quiché, and Mam; with the workers of the Summer Institute of Linguistics in Mexico for all the Maya languages there. In Mexico, materials for volume 26 of the University of Chicago's *Microfilm Series on Middle American Cultural Anthropology* (texts and dictionaries in Chol, Tojolabal, and Tzotzil) were obtained from the Summer Institute and were filmed; other Maya language materials of Summer Institute workers will be added to this series from time to time.

8.0. ETHNOGRAPHY

8.1.

ROBERT REDFIELD

Sociological Investigation; Yucatán

YB 30:122–124, 1931

There is a marked disposition among social anthropologists to make their work a contribution to the understanding and control of life; probably it does no harm to be a little presumptuous. At any rate, few students of the simpler peoples want their work to result in merely a miscellany of curious information, and many quite definitely strive to derive from it general knowledge of human ways. No behavior in nature so challenges the usefulness of the scientific method as does human behavior. Some of us are disposed to accept that challenge, and to turn our scientific interest toward the “what happens, and why” in the ways of men.

If we are interested in what happens, it seems best to study it while it happens. It is true that we want to know the history of the people we are studying, because that helps us to learn what experiences have brought about their present characteristic behavior. But the history of non-literate peoples is poor in intimate materials. Many more facts are knowable about changes that go on before one’s eyes.

There is reason to suppose that such changes may be more easily understood in simpler societies, where the factors in the situation are relatively few. This gives the student of the folk peoples an advantage. In Yucatán, we believe, for several reasons this advantage can be pressed. The essentially insular character of Yucatán defines the field of study. The history of the Maya and of the contact of Indian and Spanish civilization is being intensively studied by competent specialists. There exist within a small area communities exhibiting a range of civilization from the primitive tribe to the urban aggregate. And finally, many of these communities, under the influence of modern industrial civilization, are undergoing striking changes.

With this viewpoint and these hopes, we have begun the study of selected communities that lie along this range of civilization. We are seeking to make the studies of the separate communities comparable with one another and we are trying to describe changes that are going on. The entire resulting description

should have a dynamic character; it ought to sketch out a process, the process of becoming civilized.

This year Alfonso Villa and I pursued a study of Chan Kom, a village lying about 12 miles [19.3 km] south of Chichén Itzá. Circumstances there were extremely favorable, due to the goodwill gained in the neighborhood by Miss MacKay of the Chichén Itzá staff and to Villa's two years of selfless service in the village as a teacher. We were therefore able to study the community with the friendly cooperation of its inhabitants. Materials were collected representing the entire round of life of the people. Included are detailed materials on the utilization of the land and the expenditure and division of labor, and considerable information on both Christian and pagan elements in the religious belief and practice.

We tried, furthermore, to report not merely the abstract patterns of custom, but also the living community which is the carrier of those customs, and the changes which both customs and community are undergoing. The particular interest of Chan Kom in connection with the larger project lies in the fact that Chan Kom stands right on the frontier of changes now going on among the Maya. The people are still a homogeneous folk people, dependent upon oral tradition and largely isolated from the world. Yet they are deliberately seeking to relate themselves to the more modern civilization of the towns, encouraging education, sanitary reforms and horticulture. In organizing a cattle cooperative to care for cattle offered by the Socialist government of the State, the villagers arranged to have the shaman perform the ceremony of blood-sacrifice to exorcise evil spirits from the new herds. Chan Kom looks both forward and back.

This Chan Kom study is to be kept unfinished, for the full significance we would like it to have will be realized only if it fits into the series of similar studies forming a description of culture and civilization in Yucatán. A part of my time was therefore spent this year in preparing for these other studies. We wish to include some study of Mérida, for only there is the full participation influence of modern industrial civilization realized. Therefore I made acquaintance with that city and with Mrs. Redfield's help, investigated the sources of materials there available and collected documentary and statistical data. We made some study of the newspaper and other published materials, obtained data on the distribution of civilization within the urban area, and learned something of the location and nature of the sub-communities in the city. In January 1932, Dr. Asael T. Hansen is to begin field work on the project; he will carry forward the study of investigating one sub-community and will probably do the same in a village of peons near Mérida. We plan to include in later years one of the mestizo towns where

the simple folk culture tends to acquire some of the complexities of civilization.

Dr. Hansen's study will represent one step up from Chan Kom. One step down is represented by Indian villages in Quintana Roo. Villa and I visited the northernmost villages of this area in April 1931, and have laid plans to begin work in them in November or December of this year. The Quintana Roo Maya have customs much like those we find in Chan Kom, containing more archaic features, but the temper of the community is entirely different. Most of the people do not welcome modernization, and many of the villages are definitely hostile to it. These Maya face not the future, but the past. Their social milieu is not one of settled towns people much like themselves, as in Yucatán, but of traveling traders and migratory chicleros. They retain, therefore, their own intervillage organization; a sort of theocratic-military federation under the dominance of secular shamans and chieftains grown wealthy as chicle contractors. Here the Chan Kom study should find contrast; here Villa is to begin work next fall. Still later, we may step down again and study a still more primitive community farther south or southwest in the Maya area.

8.2.

ROBERT REDFIELD

Ethnological Research

YB 31:111-114, 1932

The studies we have begun of the contemporary people of Yucatán are guided by two primary assumptions. One assumption is that although scientific interest in the peninsula had its beginning in connection with the ancient Maya culture, and although it is certain that study of the present day Maya will throw light on, the Indians of the times before the Conquest, nevertheless, the ultimate aims of science are more likely to be served if the student describes what is actually before him. If a student of society should report only what is apparently aboriginal in the contemporary culture of Yucatán, he would be like one charged to study and describe the structural mechanics of a building, who would ignore everything in the house but heirloom's brought over on the Mayflower. To learn the rules by which a thing works, you have to study the thing as it works before your eyes. The Maya elements in the contemporary culture of Yucatán are now thoroughly in-

tegrated, with elements of European or modern American origin. The life in the villages is tied up with institutions that have their roots in the capital city, and with an economic system that includes the whole world.

The other assumption is to the effect that a description of contemporary Yucatán can be more than a mere depiction of a static condition, and that by virtue of the fact that the area, geographically homogeneous and racially simple, contains within it communities ranging in complexity from the family or tribal group of primitive Indians to the large urban aggregate which is Mérida, the capital, the description can, in effect, describe a process. If studies be made of communities along this range of sophistication, and these studies be made comparable, the comparison should constitute a summary account of how man gets to be civilized, or, what is the same thing, urbanized. Instead of making a picture, we will make a moving picture. It will show some of the changes that take place as the isolated community, economically independent and non-literate, gives way to the complex and heterogeneous city.

The ultimate importance of this description of process will result, we hope, from the interest we have in making the description a little more than the account of a unique series of events, more than a mere inventory of ethnographic fact. We should like it to emphasize the resemblances and the repetitions of the cultural process. We want it to group and to classify. We want to see what there is that is alike in the various instances of becoming civilized, both as among communities within the peninsula, and also as one compares the situation in Yucatán with similar situations elsewhere. We shall be describing one case, but always with an eye out for other cases of the civilization process in other places. The moving picture will, we think, have a certain flavor of familiarity to those who have seen the theme, folk-to-city, employed on some other stage. Our studies of this special concrete situation are made orderly and systematic by centering our attention upon the contrast and the transition between two ideal types of societies: the folk culture, non-literate, unsophisticated, with a simple division of labor and homogeneous and relatively immobile customs involving many sacred sanctions; and, on the other hand, the city civilization, literate, sophisticated, with a complex division of labor, heterogeneous moral and religious customs and a predominance of impersonal contacts and secular institutions. In this way a regional survey can become, in effect, a scientific hypothesis.

We have begun this task at the two ends, by initiating studies of Maya villages and by investigating the Yucatecan society as a whole, with special reference to the one large city. In 1930–31 Alfonso Villa and

I studied Chan Kom, a Maya village in the Valladolid region, and Mrs. Redfield and I began the study of Mérida. During the year 1932 Dr. Asael T. Hansen and Mrs. Hansen carried forward the work in Mérida. They concentrated special attention upon the barrio of Santa Ana, a part of Mérida that has undergone great changes due to the growth of the urban area and the introduction of recent elements of outside civilization. These changes have not gone on evenly, and have resulted in a condition of extreme diversity. A study of this barrio thus reveals the range of culture and social classes in the city. The old aristocracy are present, many of whom have traveled and studied in Europe and the United States and who participate in the currents of world civilization. Two streets in Santa Ana are occupied by middle and upper middle-class people, and in the rest of the barrio live lower middle-class and lower-class people. Here persist many elements of folk culture, such as the thatched hut and the mestizo costume. The herb doctor competes with the modern physician, and black magic is much feared. But elements of urban civilization are pushing in and displacing the folk culture. No one ever builds a new house of thatch; very few children dress in the mestizo costume; and black magic is becoming a superstition.

Dr. Hansen made an intensive study of one block on one of the middle class streets. Here his material is so complete that he can compare cultural features of the various households in tabular form. At the same time his less exact materials, derived from personal association with people in many walks of life, are being classified according to a scheme of presentation that is guided by the problem central to the various studies: the transition from folk culture to city civilization. It is Dr. Hansen's plan to spend the second half of 1932 living in and studying another Mérida area in which there is a higher degree of homogeneity. In this area dwell lower-class people who have not taken on so much of the urban civilization. Such an area will contrast strongly with the block already studied in Santa Ana. By judicious sampling of the metropolitan region, it is believed that we can fairly represent the situation in the city.

While Dr. Hansen and his wife have carried on the field work, Mrs. Redfield and I have been working on the project during the summer of 1932. Mrs. Redfield has undertaken the study of the Mérida press, daily, weekly, and monthly. From these periodicals she clips relevant materials, and classifies them according to the same scheme which the Hansens are using in the field. In this way it will become possible to combine two different sources of information: the materials gathered in field work, and published documents.

I have been employed, during the summer, in a study of the materials collected last year by Villa and

me in Chan Kom, and in writing them into an ethnographic monograph descriptive of that community and its culture. I plan to take this manuscript back to Yucatán next year, and by going over it in the field, substantially to extend its contents and to check its accuracy. The preparation of it has made it possible for me to see the weaknesses in the work already done. As it now stands the monograph is of value as a study of a peasant community. But the worth of this particular study will be increased as we make similar studies of other villages at different levels of economic and cultural development. Writing up these notes has helped to guide the other studies to comparable forms.

The next village study proposed is of a Maya settlement in Quintana Roo.¹ This work will be begun in December 1932, by Alfonso Villa, who, from his years of service, first as a rural teacher and then as an ethnological assistant, has already a knowledge of Maya customs and language. In preparation for intensive work, Villa made a five weeks' trip of ethnological reconnaissance in little known parts of the Territory. He traversed most of the region north of and including Petcacab, west to and including Xiatil (just east of Lake Chichancanab), and south of a line drawn from Valladolid to the south end of Cozumel Island. He visited 28 Maya settlements. Concerning this part of the Maya territory we have almost no ethnological information. Villa prepared a satisfactory map of the villages here, and made a good photographic and journal record. The villages are grouped into three political-religious divisions, each under the dominance of a native priest and a native chief, who are resident in one of three sacred settlements, each guarding a shrine in which is a cross that utters or writes oracular pronouncements and instructions. Villa visited one of these shrines, and determined the allegiance of each of the 28 villages to one or another of the shrines. The central of these three groups of villages is least affected by schools and other recent influences and Villa selected one of the villages of this group for future study.

Although most of his time was of necessity spent in traveling through the bush from one settlement to another, Villa collected enough casual ethnological information to suggest the existence of many problems for further investigation. It appears almost certain that the extended domestic family is much more important in the Territory than it is in Chan Kom, where we find that institution largely superseded by the small individual parental family. It is also probable that in some cases in Quintana Roo the young married man works for his father-in-law to earn his bride. Villa also received accounts of the New Fire (*Tumbul Kak*) ceremony held on Holy Saturday, when the fires are extinguished in all the houses and are re-lighted from a new fire, ceremonially kindled, at an hour announced from a

consultation of the stars, by means of a fire drill operated by certain personages known as Hot Hands (*Choco Cab*). Here we apparently have another interesting instance of the syncretism of pagan and Catholic custom.

NOTES

1. A determinant is any date which the Maya appear to have used to declare what addition should be made to the Long Count in order to bring any specified date in the 365-day year into the same relation with the tropical year as it was believed to have possessed at the mythical start of the calendar at 13.0.0.0.0, 4 Ahau 8 Cumhu.

8.3.

ROBERT REDFIELD
Sociological Study

YB 32:100-104, 1933

The culture of the present-day inhabitants of Yucatán is not Maya, in the sense that it does not represent the ways of life of the pre-Columbian inhabitants of the peninsula. The archaeologist, but not the ethnologist, deals with this ancient and extinct culture. There is, therefore, no Maya ethnology, strictly speaking, as there is a Maya archaeology. Ethnology deals with the cultures of living peoples, and in Yucatán this living culture is neither Maya nor Spanish. It is not even quite fair to the facts to say that it is part Maya and part Spanish. When two cultures are brought together, the new culture is not the sum of so much of the one and so much of the other, but a new third thing which is an original growth rather than a mere mixture. When we say that certain elements in this present-day culture are "Maya," such as rain-gods associated with the four directions, bark-beer and bee-hives we mean only that their presence in the contemporary culture is historically due to continuity with Indian tradition rather than Spanish; but each of these traits and every other, whether Indian or Spanish in origin, has been reformed and re-defined in terms of the new traits and the other changes that have taken place in Yucatecan life in 400 years. The contact between Spaniard and Indian resulted in a new culture, the Yucatecan folk culture. Looking at the facts, one gets the feeling that most of the changes and re-definitions of meaning took

place in the first few generations after the Conquest, and that this Yucatecan culture was not long in forming. Certainly today it is very widely and fairly uniformly distributed. And today it is often difficult to say to what extent contemporary customs are derived from a European tradition or from the Indian heritage. Shall we say, for example, that the custom of bleeding for illness is Indian or is European in origin, in view of the fact that both European and pre-Columbian Maya practiced such a custom? And if we say it is Indian in origin in the village and European in the city, then what is its origin in the intermediate town? Such problems do not easily lend themselves to solution.

The project upon which we are engaged turns aside from these problems of historical analysis, and takes the Yucatecan folk culture as its basic datum. Our task is double: first to describe this culture and then to study the changes that are taking place in it as a result of the impingement upon it of influences from the city and the wider world. For, in varying degrees, the communities of Yucatán are undergoing modification, due to increasing contact and mobility. Schools, moving pictures, social and political propaganda and economic exploitation tend steadily to modernize Yucatán. The plan of study proposes the simultaneous investigation of three or more communities, affected in varying amounts by these modernizing influences, and then the comparison of these communities. Such a comparison, it is assumed, will amount to a summary description of the process of civilization, or modernization, in Yucatán. We aim to describe, in the form of a concrete instance, the transition from primitive (folk) society to civilized (urban) society. Moreover, as this is a change that has taken place and is taking place in many parts of the world, it is hoped that by comparing this Yucatecan instance with others elsewhere, a more general (and in this sense more scientific) description of the process of civilization can ultimately be realized.

The study of this basic folk culture was initiated in 1930–31, when Alfonso Villa and I began work in Chan Kom, a village just south of Chichén Itzá. In the following year Villa undertook trips of ethnological reconnaissance among the still more isolated villages of the forest hinterland to the south, and Dr. Asael T. Hansen began the study of Mérida, the one city of the peninsula. The year just ending (1933) saw the work in Mérida carried forward by Dr. Hansen, while Mrs. Redfield and I added a fourth community to the series of comparable units by making a short study of Dzitas, a town of mixed bloods, situated on the railroad immediately north of Chichén. Mr. Villa made one extensive trip into (what was until recently called) Quintana Roo, and two shorter trips. He further strengthened his position among the suspicious Indians of this re-

gion, and secured some ethnological data, but the poverty of the natives there made it impossible for him to remain for more than a few days in his role of merchant, and indicated the advisability of postponing intensive work among them until chicle exploitation should be resumed. Accordingly, Mr. Villa spent six weeks making a survey of the Cobá-Yaxuná sacbé and devoted the remainder of the field season to beginning a study of the shaman-priests or *h-mens* of Yucatán, both of the role of these important personages in the village life and of the more or less esoteric specialized lore which they possess and transmit to their successors. In this he was greatly aided by the acquaintance he already had with several of these *h-mens* and by his knowledge of the Maya language. He visited seven or eight of the most renowned *h-mens* of the Valladolid region and began the collection of data which will make known to us the pagan religion as it is understood and practiced by these specialists.

Dr. Hansen, assisted by Mrs. Hansen, continued the study of Mérida, remaining in that field of work during the autumn of 1932 and the first eight months of 1933. The Hansens took up their residence in a different part of the city, on its western edge, and a study they made of the block in which they dwelt, compared with a similar study made the previous year in the barrio of Santa Ana, and with a shorter study made this year at their direction of a neighborhood in the south side of Mérida, enabled them to know something of the range of regional differences in culture and of local homogeneity within the city. These differences turn out to be fairly small. Indeed, as the work progresses we are struck with the essential uniformity of the basic culture. Traits found first in Chan Kom turn out to be present as well among the lowest classes in the city, even though these city-dwellers are from old urban families with much white blood and with Spanish surnames. The ideas of disease and its treatment, the practices at childbirth, even such apparently Indian customs as the little ritual known as *hetz mek*, wherein the infant is handed objects supposed to assure his success in later life occur in the city. But the linkages and emphases of the customs are very different as city is compared with village; and it is the definition of these differences that constitutes the description of the civilization process to which I have already referred as the goal of these investigations.

The Hansens' materials are particularly rich in respect to the topics of sickness and its cure and of the family. Here enough has been learned to permit of a statement with some assurance as to the essential attitudes and institutions, and of the variations in respect of these elements of culture as one social class in Mérida is compared with another. Furthermore, enough historical material, for the recent period, has been obtained,

either from informants or from documentary sources, to add a temporal dimension to the Mérida study. Dr. Hansen is preparing an historical account of recent changes in kinship and the family. In this investigation, the relation between technical changes (capitalistic exploitation of henequen; wealth and foreign travel) and familial attitudes becomes apparent. Dr. Hansen's investigation of sickness and its treatment in Mérida also begins to reveal how the folk practices, especially those carried on by the village h-men, have become assimilated with and modified by elements introduced from other sources, such as medieval European magical handbooks, and a spiritualistic cult introduced by the sophisticated but taken over and reinterpreted by the masses.

During the first month of this field season I was engaged in a revision of a manuscript prepared in 1932 and embodying the materials collected by Villa and me in Chan Kom. In this revision I was assisted by Don Eustaquio Ceme of that village, who spent the period with me in Dzitas. The last month of the season I employed in a visit of general reconnaissance in the highlands of Guatemala, with a view to the possible extension of the ethnological work into that field. The remainder of the winter and spring months Mrs. Redfield and I devoted to a brief study of Dzitas, as a town intermediate on the scale of modernization between Chan Kom and Mérida. Here the social and cultural range was explored by a preliminary house-to-house canvass to determine the name, occupation, language and costume, whether mestizo or *catrin* (folk costume or "store clothes") of the occupants. This census guided us to a fair sampling of the community in our subsequent more intimate dealing with informants and in our direct participation in domestic activities, and also led to an understanding of the interesting situation with regard to class and race in Dzitas. Here assimilation and amalgamation have proceeded so far that—setting aside the more sophisticated viewpoint of a few teachers and officials recently come from the city—all the people, whether predominantly Indian or predominantly European in blood, and whether Indian or Spanish in surname, participate in a single culture. Even in ceremonies held in the fields to the pagan agricultural deities, mixed bloods of Spanish surname take part along with those more apparently Indian. In spite of this, however, there endure the vestiges of a class system based on race, as socially defined: persons with Spanish surnames, no matter what their color or occupation, are *vecinos*; while those with Indian surnames are *indios*. The mobility of very recent years is bringing the *indio* into specialized occupation and into residence near the center of town, and the Revolution gave him the offices of municipal government; nevertheless the older *vecino* culturally much

the same as the *indio*, tends to resent this encroachment upon what two generations ago was recognized, by numerous social usages, as his superior status, and he thinks of the *indio* as a socially lowly class. Thus in Yucatán the class distinction between mixed-blood and Indian outlived the cultural differences between them; but this distinction, as a definite class distinction, has vanished in the city and is disappearing in Dzitas. The situation contrasts with that in Guatemala, where the difference between *ladino* (corresponding with *vecino*) and *indio* (*indígena*) is exceedingly sharp, and where it is a difference both of culture and of class. In Guatemala, contact between (Indian and Spaniard made two cultures; in Yucatán it has made one. This presents for investigation, a problem in the field of race relations.

During the season, Dr. Hansen kept in frequent communication with us, so that a beginning was made with the comparative treatment of the materials gathered separately in the three communities of Mérida, Dzitas and Chan Kom. Taking the chief institutions one by one, we began a tabular summary of the characteristics and functions of each. In this way differences between one community and another became sharply apparent; the summary comparisons became, in effect, hypotheses for further testing. The statement of this preliminary comparison must find a place elsewhere than in these pages¹ but among the general differences as one moves from village to town and then to city are: increasing cultural heterogeneity; increasing division of labor and the development of secular specialists at the expense of sacred and traditional functionaries; breakdown of a close familial organization appropriately supported by sacred ritual; decreasing influence of religious sanctions upon conduct; conversion of the annual fiesta from a sacred rite to a mere holiday or commercial opportunity; and the changing quality of the agricultural rites, which are acts of true piety in the village, mere magical acts of safeguard in the town, and disappear with agriculture itself, in the city, the deities to whom in the village these rites are addressed becoming mere evil or mischievous spirits, or characters in entertaining tales. Unexpected to me was the apparent increase of black magic as one goes from the village to the city. The applicability of this generalization with respect to other communities must be tested, and the reason for it is to be sought. It may be connected with the spread of foreign magic into Yucatán by way of the city, and it may also be any, in the 'city environment' of aspect of the increasing mobility and insecurity a people still primitive in their mode of thinking. And this double possibility in turn reminds us of the wisdom of using both historical and sociological approach in order to get a full understanding of a social situation.

NOTES

1. Culture changes in Yucatán, paper read June 22, 1932, before Section 11, American Association for the Advancement of Science. This paper was later published in *American Anthropologist* 36:57–69, 1934, and reprinted in *Contemporary Cultures and Societies of Latin America*, Dwight B. Heath, ed.; pp. 17–29 (New York, 1965), and *Selected Papers of the American Anthropological Association, 1921–45*, pp. 192–204 (Washington, D.C.: American Anthropological Association, 1976)[ed.].

8.4.

ROBERT REDFIELD, ASael T. HANSEN,
AND ALFONSO VILLA ROJAS
Sociological Study

YB 33:101–102, 1934

The study of the contemporary culture of Yucatán was planned by Dr. Redfield, who has directed it since its inception in 1930, to include descriptive surveys of four community types: city, town, peasant village and tribal village. It was proposed to compare the four resulting surveys, and thus to define some of the variations in the basic Yucatecan folk culture and to describe its progressive urbanization. Fuller statement of the objectives and methods of this very important research, and of its bearing on Maya history, has been made in earlier reports [Chapters 8.1–8.3].

July 1, 1934, saw one of these surveys complete; a second nearing completion; a third, much briefer study, complete subject to qualification in another short period of field work; and the fourth, that of the tribal village, deferred until 1935 or 1936.

Dr. and Mrs. Redfield returned from Yucatán in June 1933, with field notes representing their summary survey of Dzitas, the community chosen to represent the Yucatecan town. During the winter of 1933–34 Mrs. Redfield prepared a manuscript representing the study of myths and tales in the town community. In July 1934, Dr. Redfield began to work up the general materials on Dzitas. It is planned to take the tentative manuscript dealing with this community to the field for revision in the spring of 1935.

The study of the peasant village (Chan Kom) was committed to manuscript during 1933 and was sent to the press in the autumn of that year. It will appear in

September 1934 as *Chan Kom: A Maya Village*, by Robert Redfield and Alfonso Villa R. (Publication 448).

Dr. Asael T. Hansen, assisted by Mrs. Hansen, brought the results of his study of the city of Mérida nearer to formulation. Returning from Yucatán in August 1933, Dr. Hansen devoted the autumn months to a first draft of a manuscript dealing with the folk in a city environment. In January 1934, the Hansens returned to Yucatán. During the following months, Dr. Hansen worked on this manuscript, turning from it to the field for new data wherever in the course of writing the study called for further materials. There were notably enriched materials on the ecological history of the city and on the culture traits of the upper classes corresponding to the customs and institutions of the masses.

A particular interest has developed in the wide scope and variety of magic in the city environment. Dr. Hansen has been exploring this aspect of the problem and has disclosed a number of leads for further investigation. One such is the apparent competition among magical techniques in the city, so that magic takes on some of the characters of a commodity. This may be related to the secularization of the folk religion in the city. Another is the importance of “triangle” situations in connection with the practice of witchcraft, and the possible relation of this association to the predominance of women in the city, and to the disorganization of the family.

In the spring of 1933, the study of the Quintana Roo quasi-tribal village, upon which Mr. Alfonso Villa has made a small beginning, was deferred, due to the unfavorable economic and political situation in the area. Mr. Villa then began a study of the role and the esoteric knowledge of the shaman-priests of southeast Yucatán. This study was in turn interrupted when Mr. Villa came to the United States for work at University of Chicago in the summer of 1933.

8.5.

ROBERT REDFIELD, SOL TAX, AND
ALFONSO VILLA ROJAS
Ethnological and Sociological Research

YB 34:135–137, 1935

During 1935 the program initiated in Yucatán in 1930 was brought nearer completion, and a new enterprise was initiated in Guatemala.

The Yucatán project calls for the study of four types of communities chosen with reference to the degree to which modern urbanized ways of living have affected the Maya-Spanish folk culture which developed in the rural villages. These four types and the communities chosen to represent them are, in the inverse order of relative isolation: the city (Mérida), a railroad town of mixed-blood population with connection on the one hand with the city and on the other with the rural Indian village (Dzitas); a village of Indian agriculturists, independent of hacienda employment and incorporated into the political and educational organization of the state (Chan Kom); and a village of politically independent, on the whole tribally organized Indians in the remote hinterland of Quintana Roo (Tusik or X-Mahben).

At the close of 1934, Dr. Asael T. Hansen ceased the work of collecting field data relevant to his study of Mérida and returned to the United States. During 1935 he devoted time free to him from other obligations to the writing of a monograph on this urban community. The central problems to which his analysis is devoted are the relation between the culture of the urban masses and that of the privileged classes, the changes in the folk culture as it appears among the urban people, and the trend of change from the older society, involving fixed social classes and the dominance of personal and familial relations, to the newer, more mobile, secular and individualistic mode of living.

The materials which Dr. and Mrs. Redfield collected in Dzitas in 1933 have now been subjected to some study and a beginning made in the writing of a report based upon them.

In the spring of 1935 Dr. Redfield was for five weeks in Yucatán, revisiting Dzitas and securing materials necessary for the completion of the report on that community. He also spent some time in Chan Kom, and collected data on changes which have taken place in that village since his last visit. It has been suggested that a restudy, or repeated restudies of one community already studied, would give a "genetic" account of acculturative change which would be valuable in the further investigation of the characteristics of this kind of social change. The data collected this year can be used to guide the planning of such a restudy of Chan Kom.

Mr. Alfonso Villa continued his studies in anthropology at the University of Chicago until June 1935, when he returned to Yucatán. In August he went into the interior of Quintana Roo and began the study of the community chosen there, for which he had done the work of reconnaissance in 1932 and 1933.

The highlands of Guatemala, preserving the richest survivals of pre-Columbian Maya cultures, beside

furnishing material to supplement archaeological work, are exceptionally fertile for social anthropological research. The highlands, in pre-Conquest days probably marginal to the high civilizations, are today populated by over a million Indians who speak Maya languages and whose lives are relatively uninfluenced by the outer world.

Studies of these Indians in particular towns have already occupied some ethnologists, but the work now being initiated by the Division represents the first attempt at systematic and comparative research.

Dr. and Mrs. Tax undertook, in November and December of 1934, a preliminary survey of the western part of the highlands; from January to June 1935 they remained in Santo Tomas Chichicastenango for more intensive work. The program calls for this alternation of systematic survey and intensive study of chosen towns, always with the dual purpose of understanding the general configuration in the light of geography and history; and advancing the solution of sociological problems for which the region appears to furnish crucial data.

The use of comparative methods, toward the latter end, is much facilitated by the division of the population into easily defined units. Due probably to the irregular topography, the people, in dialect and culture, are split into a large number of small territorial groups. Each political *departamento* is divided into *municipios*, each of which is typically homogeneous in language and culture and all of which differ from one another in varying degrees. The *municipios* are effective social segments, each tending to be specialized economically, to have its own social and religious system, its own distinguishing costume, its own dialect; each has, in addition, a strong feeling of unity and a desire to be endogamous.

In addition to the graduated cultural differences that one expects to find between contiguous ethnic groups, there are in these highlands a number of startling and fundamental, even though sporadic, variations between *municipios*. These variations, which as additions to normal differences, imbue the region with its extraordinary sociological significance, may be classified roughly into geographical, racial and historical.

The geographic differences revolve about the fact that there are, in general, three types of *municipios*. One consists of a town, which may be simply an economic and religious center unpopulated except on certain occasions and surrounding country in which the people live on their scattered farms. A second type is like the first except that there are one or more smaller villages in addition to and dependent upon the town. In the third type all or most of the people live permanently in the town and leave it when necessary, for short periods, to work the surrounding fields.

The presence, of two wide-spread racial groups brings about the second group of differences. Living side by side with the relatively pure Indians are the ladinos, who represent an old mixture of Indian and Spanish. These racial groups are sociologically important because they are at the same time economic and social classes, and in some respects almost castes. Variations occur both in the distribution and position of these classes. There are municipios containing solely Indians and others with a high percentage of both Indians and ladinos. There are municipios in which even the small group of ladinos are politically dominant, and others in which the Indians share municipal responsibilities. Furthermore, there are towns in which the ladinos form a bourgeois class and others where, like the Indians, they work their own farms and do their own chores.

Variations derived from historical accidents are less easily cataloged. First of all, the superimposition of Spanish culture (and Christianity), especially since the Indian cultures were undoubtedly already different, could not have been uniform on all the groups, and the cultures today do not contain the same amount or kind of Spanish admixture. More recent contacts and changes are no more uniform: the introduction of commercial planting, drawing some Indians to new occupations, has affected some municipios greatly and some hardly at all; intermarriage between modern Europeans and the Indians, in some cases giving rise to new social classes, has occurred in important proportions in only one region; the recent introduction of foreign goods, as well as Protestantism, has had unequal effects in different parts; military service has made inroads in some municipios and none at all on their neighbors; and, the program of Indian education, successful in some municipios, has yet to be felt in others.

These differences are largely independent, and cut across one another; but since at the same time the municipios are brought together in a network of trade relations and exist under a common government and its political and economic system, the varieties must be studied in their common cultural matrix. Such problems, therefore, as the interrelations of geography, history, and culture, the formation of classes and castes, the influences of one culture on another, the differential effects on individuals of slightly differing social frameworks, for all of which the highlands furnish pertinent data require here the combination of survey and intensive study

Chichicastenango, the object of the first intensive study, illustrates a particular type of *municipio*, so large that personal relations can not be established among more than a fraction of the people; with a town occupied chiefly by bourgeois ladinos, the Indians living

scattered through the countryside most of the time; the idea of property strong, competition keen, and many Indians landless; with Indian self-government, but subordinate to ladino officials. Since they enter as factors in the distinctive customs, local politics and social relations in Chichicastenango, it may be presumed that were even one of these features different, the tenor of the whole culture would correspondingly be altered. It therefore now becomes desirable to study a community radically different.

A preliminary survey has suggested that some of the municipios on the shores of Lake Atitlán, hardly 10 miles [16.1 km] from Chichicastenango as the crow flies, are dissimilar to Chichicastenango in almost every factor mentioned above. Intensive work in one of them may demonstrate the limits of the effects of such factors, as constituting the general social, framework on culture. Meanwhile, further survey work should point out: first, types of variation between these extremes; second, strategic locations for further concentrated research. It is planned during 1936 to conduct this survey as a joint enterprise with that of the Linguistic Project under Dr. M. J. Andrade.

8.6.

ROBERT REDFIELD, SOL TAX,
ASAEL T. HANSEN, AND

ALFONSO VILLA ROJAS

Ethnological and Sociological Research

YB 35:131-134, 1936

The field workers of this group are making studies of a number of present-day Indian and mixed-blood peoples of the Maya area with reference to two projects, one in Yucatán, the other in Guatemala.

The method and the objectives of the Yucatán project have been outlined in previous reports.¹ Of the four communities which it was planned to investigate and compare, one still remained to be studied at the end of 1935: a village of those Maya who live between Ascensión Bay and Lake Chichankanab. These Indians have remained isolated and politically independent since the War of the Castes; they are the last tribally organized Maya in Yucatán. Of the three sub-groups into which they are divided, the middle group, centering around the shrine-village of X-Cacal, was selected

for study, because it is the least influenced by changes in recent years. The natives of these villages still refuse to admit school teachers or other representatives of the Mexican government.

Due to the contacts made by Mr. Villa in his trips of reconnaissance in 1932 and 1933, and to the tactful handling of Indians from these southern villages by Dr. Morley at Chichén, Villa and his wife were able, at the close of 1935, to establish themselves in Tusik, a village near X-Cacal, in a house built specially for them by the Indians. The difficulties of carrying on ethnological work were great: the uneasiness of the Indians and their hostility to any representatives of the government; fresh developments tending to open the territory to schools, roads and direct Mexican governmental control; the uncertainties of the chicle situation. Nevertheless, Villa was able to maintain relations of trust and cordiality with the people and to secure important information, much of which will, in a short time, become forever unavailable. He made a complete census and canvass of households, indicating origin and kinship connections of all persons, for the entire group of 723 persons, living in nine settlements. He witnessed and made notes on all the principal agricultural ceremonies and obtained data many other aspects of the culture.

A striking feature is the political-social-religious organization. The five "companies" into which the sub-tribe is divided are autonomous, except in tribal affairs. Each individual is responsible only to the chief of his own company. Membership is transmitted in the male line; the companies tend to be exogamous; a woman becomes a member of her husband's company. At the annual ceremony celebrated by the entire group at the capital village all the members of each company, whether residents of one settlement or of another, are quartered together in a single structure maintained for them only. Leadership of the entire sub-tribal group is provided by the dominant company chief and a supreme religious functionary, who carries on the ritual attending the adoration of a miraculous "talking" cross. The ties of company to company and of the individual to his "state" are at once political, military, and religious.

Mr. Villa observed and studied most of the agricultural ceremonies. Many of his notes on the religious beliefs and practices have been sent to Dr. Redfield, who will begin in July of 1936 the preparation of the comparative summary account of the four cultures and communities studied, taking advantage of these new materials from Quintana Roo, and placing them beside materials earlier collected in Mérida (the city), in Dzitas (a town of mixed bloods), and in Chan Kom (a peasant village of Maya).

As was to be expected, some elements of aboriginal culture survive in the Quintana Roo villages, but

not in Chan Kom or Dzitas. Such for example, are dual military-religious life-long chieftainship; a ceremony in which is erected a *yaxche* tree surmounted by a clown impersonating *coati*; and the use of special structures to serve as lounging places for the men of each company. But it turns out to be equally true that there persist in these remote villages elements of Catholic ritual that are not practiced in towns and villages nearer Mérida. In spite of the strong pagan character of much of the culture, the people are familiar with the principal prayers of Catholic liturgy, observe Catholic ceremonies almost daily, recognize the distinction between High and Low Mass, observe Lent, Holy Week and several saints' days, make a special Communion bread and a special Communion liquor of honey and water, and practice illustrative penance by approaching a shrine on their knees. It is fair to say that these Indians are, in respect to the forms of worship, at once more pagan and more Catholic than are the people of the other communities studied. Furthermore, the Christian and pagan elements are more closely fused into a single cult than is the case in Chan Kom. It appears that in their isolation of many generations, the mode of living, as remade by missionary a conqueror, has "shaken down" into a completely integrated single mode living. This is true, of course, in Chan Kom, but it is less true there, a progressively still less true in the town and the city. The summary volume upon which Dr. Redfield is now engaged will trace the changes in disorganization of the integrated folk culture, of mixed antecedents, which grew up in the isolated villages in the centuries following the Conquest.

During the summer, Dr. Hansen resumed work, temporarily interrupt by teaching duties, on the preparation of an account of culture and civilization in the city of Mérida, which is expected to be ready for publication before the end of 1937.

The first season (1934-35) of work in Guatemala established the highland municipios² as promising, if not unique, repositories of crucial data for the solution of such sociological problems as the interrelations of geography, history, and culture, the formation of castes and classes, the influence of one culture on another, the differential effects on individuals of slightly differing social frameworks. That season centered on Chichicastenango, a populous municipio, the Indian inhabitants of which live scattered on their farms, coming together on occasions to the central town which is otherwise almost depopulated except for a group of ladino (mixed-blood) middlemen.

It was proposed this year to study, for comparative purposes, a municipio, as different as possible in these objective features, from Chichicastenango, yet historically close enough to assure a common cultural

background. To that end the field season of 1935–36 was spent by Dr. and Mrs. Tax in studying the villages of Lake Atitlán.

Lake Atitlán is not large (its greatest diameter less than a dozen miles [19.3 km]) but its circumference is divided among no less than 11 *municipios*, ten of which have their principal town near the shore of the lake. The languages of the lake towns (and of Chichicastenango as well) are closely akin. The general culture, likewise, types of food, houses, and garments, political and religious organization, general economic basis and mode of life, differs but in detail from a general pattern. Such basic homogeneity one would expect from the geographic proximity; but in at least one respect of sociological significance, the similarity could hardly have been predicted. Noting last year the lack of communal life in Chichicastenango, and the paucity there of intimate social relations, it would have been expected that, on the contrary, in these small-lake towns (with as little as a 100 houses in all, and these crowded one almost on the other) communal participation and personal social relations would be strong and frequent. This is far from being the case, however. It appears likely now that there is in Guatemala a tradition of individualism and formalism so strong that it survives in seemingly the most adverse conditions. What is most remarkable at the lake, however, is not the fundamental sameness of the cultures but, considering that some of the towns are not a mile [1.6 km] apart, in fact are in plain sight of each other, the extent to which they differ from each other, marked linguistic differences, consistent dissimilarities in family, organization, in ceremonial life, in manners and etiquette, in morals and in morale, in kinship classifications, in land systems, standards of living and economic pursuits.

Striking differences in a setting as small and as self-contained as Lake Atitlán are certain to be spectacular. Also, they call for ready explanations. The difficulties involved, however, may be illustrated by differences in means of subsistence, which are usually tied more firmly to causes than are the others. Some of the economic differences are, indeed, attributable directly to geography. But the drastic limitations, as well, of this fact of, in history are conspicuously displayed here.

Panajachel, for example, the only town making a specialty, and this the virtual exclusion of all else, of intensive commercial gardening, has a river that makes irrigation practicable. On the other hand, the town of Santa Catarina makes a specialty of fishing and crab-fishing in the lake, but the inhabitants of neighboring San Antonio (agriculturists exclusively) with the lake at their doorsteps, are known to pass their lives, ignorant of swimming and canoeing, without ever ventur-

ing on its surface. Santiago Atitlán, located strategically in an opening to the coast, specializes in the transport of goods between coast and highlands; but to the villagers of San Lucas, even better located, commerce of this kind is "not the custom." San Pedro has most of the maguey (valued for the fiber of its leaves) that grows in the neighborhood, but the Pedranos, themselves cultivating corn and chick-peas, do little with it industrially; rather, they, sell it to the people of San Pablo, who employ themselves almost exclusively to turning it into rope and hammocks.

Nine of the 10 lake towns occupied about four months of the field season; the tenth town, Panajachel, was chosen to be studied intensively, and almost four months were thus spent. Researches in Panajachel need hardly be mentioned at this time apart from their bearing on the general study except to say that the problem, first suggested in Chichicastenango, of the races or social classes, was amended by the work in Panajachel. It now appears that there are not two classes, but three: Indians, working-class ladinos, and middle-class ladinos, the first two differing racially but both laborers and farmers, typically poor, rural, illiterate; the latter wealthy bourgeois, typically urban, well dressed, educated. Needless to say, the history of and the relations between the three classes in Panajachel demand comparative material from towns in Guatemala where one or more of the classes is living under different conditions. Meanwhile, it now appears desirable to divide the next field-season between Panajachel (and the other towns of Lake Atitlán) and Chichicastenango; studies in neither region are yet completed, and each may be expected to throw more light on the other. At the same time, it is planned to continue to undertake, each year, short reconnaissance surveys into territory still unvisited.

NOTES

1. See [Chapters 8.1 to 8.5], inclusive.

2. A *municipio* in highland Guatemala is a political unit more or less resembling a county, but at the same time an ethnic unit, the population of which is most comparable to a "tribe," with its own costume, culture, and identity. Each *municipio* has at least one "town," like a county seat.

ROBERT REDFIELD, SOL TAX,
 ASAEI T. HANSEN, AND
 ALFONSO VILLA ROJAS
Ethnological and Sociological Research
 YB 36:145–148, 1937

Previous reports have described the two research enterprises I carried on by the above four men. One is a comparative study of four communities in Yucatán: the city of Mérida, a town on the railroad, peasant village, and a settlement of semi-independent, tribally organized Maya of east central Quintana Roo. The principal objective of this study is to trace change in and disorganization of the integrated folk culture, composed partly of Indian and partly of Spanish elements, which grew up in the hinterland after the Conquest. *Year Book* 35 [Chapter 8.6] contains a summary of the accomplishments in the field during the previous season of Mr. Villa, to whom has fallen the task of studying the Quintana Roo Maya. The studies of the other three communities were completed before 1936, and a monograph on the peasant village, Chan Kom, has appeared. Mr. Villa's field work was finished in the winter of 1936–37. As this brings to an end the collection of data required for the study as planned, no further reports on this project may be expected until the results appear in volumes now in preparation. These are three: a monograph on the city of Mérida by Dr. Hansen; a monograph on the X-Cacal cacicazgo of east central Quintana Roo by Mr. Villa; and a summary and comparative volume on culture and civilization in Yucatán by Dr. Redfield.

During the latter part of Mr. Villa's residence in Tusik, a village of the X-Cacal group, he completed the collection of materials in such a way as to insure a point-for-point comparison of the Quintana Roo culture with that represented in Chan Kom, the peasant village. Anticipating a more considered statement, one may set down some of the more important contrasts between these two societies:

1. The techniques practiced, the familial institutions, and the folk beliefs and other ideologies of the two peoples are so similar as to be almost identical.
2. But the political organization, and such structure as exists outside of the family, is sharply different in the two societies. The government of Chan Kom is a part of the state and national governments, and functions to express the wish of the people to identify themselves further with civilization and progress; the Quintana Roo natives rule themselves

and exclude the modern world through a theocratic military hierarchy of chiefs. This difference reflects the contrast in essential social objective, the one progressive, the other intensely conservative.

3. The religious rituals present some notable points of contrast in: a. the emphasis in Quintana Roo upon group ceremonies, especially those affecting the entire subtribe; b. the greater importance of Catholic ritual elements in Quintana Roo; c. the persistence of pagan features in Quintana Roo which are extinct in Chan Kom; but on the other hand; d. the absence in Quintana Roo of a number of pagan elements which are still present in Chan Kom. This last situation presents a special problem calling for historical explanation. Related to it is the relatively smaller importance of the shaman priest (*h-men*) in the more isolated and otherwise primitive community as compared with the corresponding situation in Chan Kom. The Quintana Roo people developed a paramount leader, sacrosanct, in the person of the functionary (*nohoch tata*) who maintains the tribal shrine and ritual. This is probably an adaptation of Christianity to primitive conditions, made in adjustment to the necessity for organizing the tribe against outside attack. Incidentally it may have brought about diminution in the authority of the more pagan *h-men*.

It should be reported that incidentally to his scientific work, Mr. Villa played a large role in negotiations between the Mexican government and these natives, leading toward a peaceful settlement of their differences with the Government, and the acceptance of ejidos, and eventually of schools. Thus the knowledge Mr. Villa obtained as to these people in the last years of their isolation became an instrument in the breaking down of that isolation. The change had to come; it is fortunate that Villa's experience could be used so that the transition might be effected with relative ease.

The Guatemalan project is formulated in more general terms. The task is to survey the cultures of the western highlands, to provide a first classification of the cultures and societies there to be found, and to define a few special problems for study. The field work has been done almost entirely by Dr. Tax. His paper (Tax 1937), published in the *American Anthropologist* for June 1937, established the municipios of the midwestern highlands as the essential natural societal and cultural units, in terms of which studies must be carried on. In 1934–35 Dr. Tax began work in the municipio of Chichicastenango. In 1935–36 he made brief studies of several of the communities adjoining Lake Atitlán, and initiated an intensive study of one of these, Panajachel. This study was resumed in the six months spent in the field from January to July 1937. The investigation this year proceeded from the general and statistical to a consideration of the more inti-

mate aspects of native behavior and belief. Living in a house not unlike those of the Indians themselves, and in the center of the Indian settlement, with the people already accustomed to the presence of strangers, Dr. and Mrs. Tax entered more fully than before into the native community. Trading with the Indians and helping them in their deals with one another, growing crops along with them, doing their bookkeeping for them and helping them in their own ways and means, all brought forth information that made more significant the market accounts and statistics, and the tables bearing on questions of production, consumption, and distribution that were otherwise prepared. Acting as godparents to Indian children, advisers to young people and their parents and in some cases even matchmakers, and aiding friends in times of sickness and death, gave the close and personal view which is essential to successful reporting of an alien social organization. Helping in, or at least witnessing, the meetings of the elders when political problems arose, did the same for political institutions. And of course participation in religious ceremonials of all kinds brought not only the natives' good will but understanding as to the relations of the sacred and the secular, of the religious and the political, and of the Christian and the pagan.

Perhaps in no branch of Indian culture, however, did the accumulation of two seasons of good will give better results than in that of folk tales. For the first time in Guatemala an aboriginal mythology was uncovered. Aside from its intrinsic interest and value (it includes origin myths, legends and tales of all kinds, and anecdotes about people living and dead) this folklore bared much of the Indian mentality difficult to uncover otherwise, and also furnished innumerable leads to previously uninvestigated fields of native belief.

Meanwhile the sociological problems previously defined were not neglected. Additional material bearing upon the nature of the municipio and the relations between municipios was gathered; also, of course, upon the nature of communal life itself in Panajachel. One important group of problems earlier recognized arises out of the fact that the midwestern highland societies are not composed solely of Indians, but also of those mixed bloods of Spanish language and (largely) Spanish culture called ladinos. Earlier work in Chichicastenango and in Panajachel had established the existence of a rough three-class system, consisting of the Indians, the rural agricultural ladinos, and the more commercial ladinos of the towns. It was desirable to get a view of Lake Atitlán society from the standpoint of some of the ladino communities. To this end Dr. Redfield, accompanied by Mrs. Redfield, spent nine weeks in Agua Escondida on Lake Atitlán, just above the Indian village of San Antonio and not far from Panajachel. This situation made possible frequent

interchange of questions and advice between, Dr. Redfield and Dr. Tax. Dr. Redfield made a short study of the ladino culture and society, with emphasis upon the roles of the Indians and ladinos in the common society they share. This resulted in the formulation of a number of perplexing questions, statement of which will have to be deferred. The most striking single observation is the relatively slight degree to which the Indians, numerically so superior to the ladinos, are at present affecting ladino culture, in spite of the absence of race prejudice and the intimacy, with which the two groups associate.

During the year two articles, summarizing results of work in the highlands, were prepared by Dr. Tax; and his plans call for the completion of a monograph on Panajachel before again taking the field. He then proposes to return to Chichicastenango for a season to complete, if possible, the work begun there in 1934–35; but whereas at that time residence was maintained in the town itself, it is hoped that now a suitable place in the country region, where the study may be rounded out, can be found. Dr. Redfield will probably not return to Guatemala until 1938–39.

8.8.

MANUEL J. ANDRADE, SOL TAX,

ASAEL T. HANSEN, AND

ALFONSO VILLA ROJAS

Ethnological, Sociological, and Linguistic Research

YB 37:162–164, 1938

As indicated in the preceding *Year Book* [Chapter 8.7], Mr. Villa's expedition to Quintana Roo in the winter of 1936–37 completed the field work for the study of village and city life in the peninsula of Yucatán. Mr. Villa spent part of the year 1937–38 in preparation of his report on the east central Quintana Roo villages; it is expected that this will be ready for publication by January 1, 1939. Dr. Hansen devoted part time to further work on his monograph on Mérida; this should be ready in 1939. In the summer of 1937 Dr. Redfield began the preparation of the summary and comparative volume on culture and civilization in Yucatán.

The comparative study of highland societies of Maya peoples was prosecuted during the year here

reported by Dr. Tax and by Mr. Villa. Dr. Tax's year was chiefly devoted to preparing for publication material collected during the two previous seasons in Panajachel, Guatemala. After returning from the field in June 1937, field notes and data contained in such forms as genealogies, schedules, and maps were organized. At the same time a draft of one chapter of the report was written to see if the purely cultural data, the knowledge, beliefs, technology, science, values, and modes of behavior, could not be best presented from the native point of view almost as if an Indian himself were writing it. Since the method appeared fruitful, it is being continued.

During the last six months of 1937 Sr. Juan Rosales, an Indian of Panajachel trained in field methods by Dr. Tax and Dr. Andrade, remained in Panajachel to collect additional data and to resolve questions put by Dr. Tax. This necessitated considerable correspondence. At the same time, Mrs. Tax devoted herself to notes transmitted by Rosales.

At the end of December, Dr. Tax left again for Guatemala, taking up residence in Panajachel. During the three months that followed, he accomplished three missions: first, he filled in and completed his studies of Panajachel culture, clearing up doubtful points for his report; second, he installed Sr. Rosales in the town of San Pedro La Laguna, there to do an ethnological study under his direction, and conferred with him a half-dozen times both in San Pedro and in Panajachel; and third, he made practical arrangement, for his and for Dr. Redfield's next field seasons. In the course of this work much was learned about house building and about the relations of Indian and ladino laborers and artisans in Agua Escondida; and as a house in Chichicastenango was taken only after many vain attempts to obtain land or a house owned by Indians, considerable new insight into Chichicastenango attitudes and modes of living was attained.

At the beginning of April Dr. Tax returned to resume work on his Panajachel report, now devoting himself to writing. By the end of June something more than 200 pages of typescript were ready and almost as many more in various stages of preparation. Plans call for the virtual completion of the report by the beginning of October, when Dr. and Mrs. Tax will resume work in Guatemala, returning to Chichicastenango to complete the study begun there in 1934-35.

By this time the sociological and ethnological problems to which attention is being directed are more clearly delineated, and the work should go on more rapidly. By the end of another year intensive studies of three communities (Panajachel, Chichicastenango, and San Pedro La Laguna), representing the three linguistic divisions of the midwestern highlands, will probably have been completed; it will then be possible to

undertake comparisons of a more intimate nature than those afforded by the reconnaissance and surveys of the past.

The work done in connection with this project, as well as that done by others, notably La Farge and Schultze-Jena, has indicated many common resemblances as well as certain important differences among the Mays of the highlands of Guatemala, and the facts available have further suggested that the peoples of eastern Chiapas form a part of the same general type, and region. Accordingly it is desirable to extend the guided sampling of Maya ethnology to Chiapas. Notes on the Tzeltal, Tzotzil, and Chol have been provided by Pineda, Starr, Blom and La Farge, Becerra, and others; but the information provided in their notes is inadequate to enable us to determine the significant problems in this area. Accordingly Mr. Villa spent two months early in 1938 making a reconnaissance of Tzeltal settlements. San Cristóbal de Las Casas served naturally as a base. Fifteen communities, from Amatenango on the south to Petalcingo on the north, were visited; these included both highland and lowland settlements. From a few hours to several days were spent in each community. Mr. Villa strove to secure his ethnographical information from the Indians, rather than from the ladinos, and to investigate matters such as type of settlement, Indian-ladino relationships, and form of government, as are summarized for the communities of the midwestern highlands of Guatemala in a recent paper by Dr. Tax (1937).

It is expected that the material secured by Mr. Villa will be published in a short article, but some of the suggestive findings may be mentioned here. Brief mention of Indian surnames among the Tzeltal is made by Starr; nothing is said on the subject by Blom and La Farge. Villa has established the fact that the highland Tzeltal have exogamous surname groups; the names are descriptive, or refer to animals or plants. Furthermore, certain of the highland villages are divided into antagonistic subcommunities (*calpules*), one with lands to the north, the other with lands to the south. In Oxchuc a principal annual ceremony attends the transfer from one calpul to another of a certain sacred book. This book, a manuscript containing apparently orders set down by Spanish authorities in the seventeenth century, is kept in a special sacred structure. Villa obtained further information on the 19-month calendar; it is apparent that it is still used in connection with the agricultural round.

It is expected that this reconnaissance will be followed by a more intensive study, to be carried on by Mr. Villa, of one of these Tzeltal communities.

Dr. Andrade continued the preparation of his linguistic manuscript of Yucatec; it is expected that it will be ready for publication in the spring of 1939.

8.9.

ALFRED V. KIDDER
Sociology and Linguistics

YB 38:254–258, 1939

Although the attention of the historians has naturally so far been focused largely upon the earlier phases of the post-Conquest period, their findings have cross-checked most interestingly with those of Dr. Redfield and his group, who, since 1930, have been observing and recording conditions among the living peoples of Yucatán and Guatemala.

At the time that arrangements were made with the University of Chicago for Dr. Redfield to devote some months each year to directing and taking part in the ethnological wing of the Division's program, he made it clear that the work (which began in Yucatán) must be guided by two primary assumptions. One assumption is that although the Institution's interest in the peninsula had its beginning in connection with the ancient Maya, and although it is certain that study of the present-day Maya will throw light on the Indians of the times before the Conquest, nevertheless, the ultimate aims of science are more likely to be served if the student describes what is actually before him. If a student of society should report only what is apparently aboriginal, he would be like one who, charged to analyze the structural mechanics of a building, would ignore everything in the house but heirlooms brought over on the Mayflower. To learn the rules by which a thing works, it is necessary to study the thing as it works before one's eyes. The Maya elements in the contemporary culture of Yucatán are now thoroughly integrated with elements of European or modern American origin. The life in the villages is tied up with institutions that have their roots in the capital city, and with an economic system that includes the whole world.

The other assumption is to the effect that a description of contemporary Yucatán can be made more than a mere depiction of a static condition, because the area, geographically homogeneous and racially simple, contains within it communities ranging in complexity from the family or tribal group of primitive Indians to Mérida, the large urban capital. If comparative studies are made of this series of communities, we shall acquire most valuable information upon a process of social evolution typical of large parts of Latin America and, indeed, in its trend toward urbanization, characteristic of the whole modern world.

In accordance with these principles, Dr. Redfield organized a survey of Yucatán which included re-

search upon groups at various stages of advancement. At the foot of the ladder were the Maya of the remote villages in the eastern forests, people who, since the general revolt against the whites in the 1840s, have never been reconquered and have held themselves aloof from Mexican influences. This work was carried on through several seasons by A. Villa R. The next upward stage was represented by Chan Kom, a small pure-Maya settlement which was just beginning to feel the impact of the outside world. Still farther within the zone of modern influences was Dzitas, a small town on the railroad, preponderantly Maya but with a sprinkling of Latins. There Dr. Redfield lived with his family for several months. Completing the ascent to urbanization was Mérida, the capital, where A. T. Hansen spent two years in studies of a class of society. A report upon Chan Kom by Dr. Redfield and Sr. Villa has been published and manuscripts upon the other communities are in preparation together with a concluding work by Dr. Redfield, summarizing the results of the whole investigation.

While the survey of Yucatán was still in progress a similar undertaking was begun in the highlands of Guatemala, a region largely populated by Maya-speaking Indians, but one in which environment, pre-Columbian events, and post-Conquest history have combined to produce modern conditions very different from those obtaining in the peninsula. Sol Tax, who joined the Division in 1934, has devoted himself entirely to the Indians of this area, and his work has been supplemented by investigations by Dr. Redfield of the life of the lower-class mixed-bloods or Ladinos, who form a connecting link, culturally, between the Maya and the ruling whites.

Dr. Tax, during the past five years, has made his headquarters in the central western highlands, studying, intensively Chichicastenango in the Quiché country and the Cakchiquel town of Panajachel on Lake Atitlán. He has also done comparative work at the several other communities of the lake district.

In the winter of 1938–39 Dr. and Mrs. Tax re-established themselves at Chichicastenango. Dr. Tax revised previously collected materials on this town, resumed preparation of a monograph on Panajachel, and supervised the activities at San Pedro, on Lake Atitlán, of Juan Rosales, an educated Panajachel Indian who has for several years been of great assistance in gathering linguistic texts for Dr. Andrade and ethnological data for Dr. Tax. Dr. Redfield devoted part of his time to further study of the Ladino culture of the lake area and part to work on the manuscript embracing the final results of the Yucatán project. Sr. Villa spent the year in Mexico and the United States, studying at the University of Chicago and completing his report on the primitive Maya-communities of eastern Yucatán. At

the request of the Mexican Government Sr. Villa has been detailed to assist the Mexican Department of Indian Affairs in a survey of the Totonac peoples of Veracruz.

With reference to the study of the contemporary Maya society of the Guatemala highlands, the present plan is for the preparation of from three to five publications: 1. A general monograph on Panajachel (Tax); 2. A special monograph on the economic life of Panajachel, to be prepared so as to bring it into comparable relation with similar studies of modern communities in other parts of the world (Tax); 3. A descriptive monograph, to be written in Spanish for the value it is likely to have for Guatemalan and Mexican students, on San Pedro Atitlán (Tax and Rosales); possibly, 4. A publication of such aspects of the life of Chichicastenango as are well represented in Tax's materials (Tax); and possibly, 5. A study of the Ladino-Indian community of Agua Escondida (Redfield).

The study of these present-day Guatemalan societies is in need of cooperative planning. In recent years ethnological research has been carried on in the highlands not only by this group of students but also by others not connected with Carnegie Institution. It is desirable that the knowledge obtained and largely unpublished by all recent workers in the field be brought together and exchanged. This can best be done in an extended conference. Such a conference should go far to clarify problems in the "field" by making more apparent than is now the case which elements are widespread in the area and which are local, and by emphasizing the more important lines of inquiry. Extensive survey should be combined with intensive research on selected communities. But until it is known what problems are important, it will not be possible to plan the survey wisely nor will it be possible to know which communities should be chosen for intensive study.

The experience to date of Dr. Redfield and Dr. Tax suggests that further prosecution of certain lines of research would go far toward providing better understanding of social conditions in the Guatemala highlands:

1. The Existence and Approximate Limits of Subcultural Areas in the Midwest Highlands. We do not know if the similarities and differences of the cultures of the municipios are such that the latter can be grouped into units of contiguous jurisdictions. Some of the facts which must be taken into account in approaching an answer to this question follow: a. In some municipios the Indians live in towns and work the surrounding fields by the day; in others, the Indians have their homes and their farms in the open country and come to town only on special occasions; in still others of either type there are settlements subsidiary to the town; and other municipios (in fact most) are combinations of the other types. In the

area so far visited and studied, there are three islands of the first kind of municipio in a sea of the second kind. One island consists of three towns south of Quezaltenango; another of the 10 towns of Lake Atitlán; the third of at least some of the towns of the department of Sacatepéquez, just west of Guatemala City. In at least the first two cases the condition of the Indians living in towns is probably explicable on the basis of peculiar topography; the third case has not been studied; b. Municipios tend strongly to be individually specialized with regard to the ways of making a living. Some of these distinctions are closely related to geographic differences, as that between coast lands and highlands, but others are not. We shall probably be able some day to mark off distinctive trade regions; c. Each municipio differs from many or all others in dialect, and general culture. These are not dissimilarities merely in costume and in saints' days but also in many details of social customs, in kinship classification, etiquette, and ideals of social behavior; d. Some of the differences in Indian culture are probably attributable to "ladinoization." It may roughly be said that there are areas where the Indian culture is "purer" than in others. The differences among the municipios studied appear to be in details, apparently in all phases of the culture. But in some details the variations seem important, as for example that between communal house building and individual house building (San Pedro vs. Panajachel and Chichicastenango); and in some phases of the culture the peculiarities seem greater than other phases (for example, there seems to be more to sorcery and shamanism in general Chichicastenango than in either San Pedro or Panajachel). Our problem is to plot differences, then with samples extend our studies to other towns (like border towns) of the region to see what kind of areal consistency they have; it is not unlikely that we shall find that subculture areas will coincide with language areas, in which case the come of ethnological (historical) importance.

2. The Fundamental Forms of Social and Politico-Religious Organization. In each of municipios that we know there is an institutional configuration consisting of a. formal kin and local groups and b. a structure consisting of separable but dovetailing political and religious organizations. In is probably the basic theory of Indian social organization, the two elements are inextricably bound together in one system which for its functions, first, the control of individual conduct and, second, the performance of services deemed necessary to the material and spiritual well-being of the community. In this frame of reference, the major problem is to determine by comparative (and, where possible, historical) methods what the basis system is and how and why its manifestations vary from municipio to municipio.
3. Economic Organization of the Region. One problem here is the distinction between the geographic and the more purely traditional factors in bringing about

the economic, specialization of Indian communities, aside from the effects of altitude, natural resources and quantity and quality of land, there are certain differences of economic organization which are not so directly attributable to the habitat. Contiguous municipios with closely similar resources vary sharply as to the extent to which these resources are exploited.

The full explanation of municipio specialization must take into account that, among other factors, a. the economic specialization of the municipio is an aspect of its general cultural individuality; b. the municipios are specialized with reference to crops, industries, trades, merchandizing, and labor, each of which requires separate treatment; c. in addition to special circumstances of resources and geographic position that must be taken into consideration in individual cases of specialization, there are some general factors encouraging or discouraging the adoption of new means of making a living. Among the discouraging factors is the endogamous tendency of the municipios, which, since arts and techniques are largely transmitted from parents to children, tends to perpetuate specialties. Another is the competition that the innovations meet in existing means that are supported by tradition. A third is the shortage of capital that can be risked in innovations in an economy so close to the subsistence level. On the other hand, among the factors encouraging change (and economic homogeneity) may be mentioned the continuing contacts with other municipios having more profitable specialties, especially since such contacts exist in a free capitalism and together with the desire of individuals to improve their positions.

4. Problems of Ethnic Relations Between Indian and Indian, and Indian and Ladino. Consideration given by this group of workers to the latter half of this problem suggests the following two broad generalizations as a basis for the study: a. The Ladinos and Indians of the region have at one and the same time characteristics of distinct cultural groups in process of assimilation, and characteristics of social classes. An investigation of the situation in this regard in other selected communities in Guatemala should provide us with a series of instances ranged in an order of difference as to the two characters: separate cultural groups or well-defined status groups in a society with a single culture. Comparison of such instances would give knowledge as to how this transition, which we know to have occurred a great number of times in the recent history of our Western world alone, may come about; b. The relations between Ladinos and Indians in this area are substantially without conflict. Nor is there any apparent disposition for the Indians to be held in a caste-like status of lasting inferiority. The region is occupied by two ethnic groups, of which one maintains a culture much like that of the original conquerors, its members tending to identify themselves with these conquerors, while the other

group are known as natives and so know themselves. Yet they live amicably in a common territory. Why they live together so amicably, why is ethnic membership of so little social consequence, why are there no taboos or rituals or myths to maintain the superior status of the one and the inferior status of the other?

5. Problems of Culture Type and Culture Change. The general questions may be asked: To what extent do elements of culture and society found in Guatemala have a necessary or natural connection with one another? What are the factors which have favored the spread of certain elements of culture and society in Guatemala and have limited the spread of others? Suppose we are able to say: The highland cultures are highly commercial and individualistic; exterior, impersonal institutions are important in social control; there is abundant practical magic; the treatment of the supernatural is magical and practical, and does not characteristically involve strong personal experiences with the supernatural. Then it should be possible to make it clear which of the institutions and elements of culture are consistent with, perhaps functionally related to others. A detailed comparison of certain Indian cultures, selected to represent differing degrees of intimate contact with the Ladinos, would probably give us some understanding of characteristic ways in which older culture elements (in some cases aboriginal elements) in this area changed their nature under modifying influences. For example, in Panajachel the group of beliefs about the beings inside the hill exists in a form which apparently identifies the hill with hill and the lord of the hill with the devil. In San Pedro the hill beliefs exist without this evidence of fusion, with European notions. Certain cosmogonic beliefs probably exist in San Pedro in a more nearly aboriginal condition than in Panajachel. The point to be stressed here is not a hope that we shall find any village in which pre-Conquest culture is approximated, but rather that by comparing the varying forms of what must be basically the same idea or institution we shall learn something of how culture changes under certain sorts of influences. It may not be impossible to learn, by such comparisons, something about the progressive disappearance of collective community ownership of agricultural land, which has probably occurred at least in the lake region.

The comparison of municipios already made, slight as it is, raises the question: What truth often made that the Guatemalan highlands constitute a region of great cultural diversity? It now appears that the local differences are accompanied by widespread and very important uniformities. Apparently the local variations in culture are of a sort that strike the observer in the first stages of his understanding of the highlands, while the uniformities appear greater after a more intimate understanding is reached. The

municipios differ in features that are conspicuous: costume, dialect, traditional dances, local products, special forms of ritual. These contrasts make the highlands appear a crazy quilt of cultures. The visitor is struck by the way in which, within a few miles, he may pass from Indians who wear one kind of costume, make houses of one form, and speak a certain language, to Indians who differ in all these very apparent respects. But it now appears to us that these obvious diversities are relatively exterior, and that with respect to characters which make for the maintenance of a common life together, the Indians, and the rural Ladinos too, may be much more alike than they are different. It might be enlightening to study some of these societies in terms of those institutions which are recognized by Indians of all communities and by Ladinos too, and which make it possible to establish relationships across local communities: buyer and seller; *recomendado*; *posada*; complaint before the *intendente*; godparent-compadre, etc. Other problems under this general head are the following: How is it that the sharing of so many common understandings between Indian and Ladino does not necessarily require that they come to agree with reference to understanding of the supernatural and as to the interpretation of Nature? To what extent is the overt rational life of the expression of personal religious sentiment and to what extent is this ritual magic initially executed by professionals? This is the question: How is the religion of the people adjusted to their highly practical and highly commercial manner of life

During 1939–40 Dr. Redfield and his associates will devote themselves to the analysis of materials, writing, and conference, in an attempt to organize themselves with reference to problems such as those above.

8.10.

ROBERT REDFIELD, SOL TAX, AND
ANTONIO VILLA ROJAS
Sociology and Linguistics

YB 39:280–281, 1940

During the year the ethnologic and linguistic research of the Division was advanced chiefly by the study of materials already collected, and by their preparation

for publication. No field work, directly within the research program of this group of workers, was carried on during the period. Dr. Redfield devoted much time to the manuscript summarizing the comparative study made of four communities in Yucatán. This manuscript has now been completed. Dr. Redfield also wrote and published a general paper, "The Indian in Mexico," for the *Annals of the Academy of Political and Social Science* (March 1940) and, with Mrs. Redfield, wrote "Disease and its treatment in Dzitas, Yucatán." Dr. Tax's presence in Chicago during the year allowed Drs. Tax and Redfield to collaborate in the review and annotation of a number of manuscripts in the field of Maya ethnology or that of Guatemala or Mexico generally: manuscripts by Professor C. L. Jones, Dr. Ruth Bunzel, and Messrs. R. Stadelman, O. LaFarge, C. Wagley, and F. W. McBryde. Dr. Tax did the greater part of this work, and in connection with the manuscript of Dr. Bunzel, on Chichicastenango, prepared, for purposes of comparison, a reorganization of data collected there by himself in 1934–35 and 1938–39; this work will continue. A major enterprise brought to completion by Dr. Tax was the editing and preparation for the press of a manuscript by Mr. Charles Wisdom on the Chortí of Guatemala.

Dr. Tax devoted most of his time, however, to preparation of his own materials. Attention was given chiefly to two monographs on the town of Panajachel, the first on economics and the second on the general culture of the community. The economics paper, initiated at the beginning of the year, was about half completed; two-thirds of the other were completed except for final revision and typing. In all, some 400 pages of typescript were prepared for the press; it is expected that by October this number will be increased to nearly a thousand. In connection with connection with conflicting data on land utilization in Panajachel, a short conference with Mr. F. W. McBryde was held in Columbus, Ohio, in March; notes were compared and difficulties successfully resolved. The only other departure from Chicago was a trip to Indianapolis in April 1 when Dr. Tax read a paper on "Acculturation in Guatemala" before the American Anthropological Association.

During the year supervision of the researches of Sr. Juan Rosales on the town of San Pedro was continued by correspondence. Sr. Rosales made Sololá his headquarters. The introductory sections of a joint monograph in Spanish were completed, but progress on this manuscript was continually interrupted by acquisition of new data on both San Pedro and Panajachel. Sr. Rosales made several trips to Panajachel, and also received informants from there, to confirm and elaborate items of information received in connection with the preparation of the two Panajachel monographs. He

also made extended visits to San Pedro, and spent considerable time with San Pedro informants in Sololá. Two opportunities in this connection were especially fortunate. First, the complete confidence of a San Pedro shaman was won, and for the first time in our experience in Guatemala full and reliable information on the esoteric aspects of his profession was obtained. Second, a literate Indian working in the town hall of San Pedro was employed to keep full daily records of court proceedings; the resulting material is an invaluable supplement of cases dealing with most phases of local Indian life. In all, no less than 700,000 words of type-written notes on San Pedro culture have now been collected.

Sr. Alfonso Villa was occupied chiefly with the preparation of his monograph on the Maya of the X-Cacal region of east central Quintana Roo. The composition of a long historical section required Sr. Villa to devote much time to the consideration of documentary sources. The Quintana Roo manuscript is nearing completion. For about two months Sr. Villa interrupted work in order to participate, as field assistant investigating the general social structure of certain villages, in the Tarascan project operated by the Mexican Government, under the direction of Dr. Morris Swadesh and Dr. Rubin de la Borbolla, in connection with its recently adopted policy of developing methods of writing and teaching in native Indian languages. In this connection Sr. Villa spent some weeks in Michoacan. He attended the First International Indianist Congress at Patzcuaro, and presented a paper on "The social organization of the Tzeltal of Chiapas."

In the spring of 1940, a Social Science Research Council fellowship was awarded to Mr. Benjamin Paul, student in anthropology at the University of Chicago, for ethnological work in Guatemala. His enterprise will be supervised by Drs. Redfield and Tax and coordinated with the field program of the Institution.

It proved impossible to assemble for a proposed conference most of the workers of the country who are active in Maya ethnology. Members of the interested group have, however, agreed to prepare topical memoranda to be used as a basis for discussion when, probably next year, the conference is held.

Dr. Andrade also remained in the United States during the year. Work on the linguistic project consisted mainly in the analysis and organization of data gathered in previous field trips. The grammar of Yucatec is almost finished.

8.11.

ROBERT REDFIELD, SOL TAX, AND
ALFONSO VILLA ROJAS

Social Anthropology and Linguistics

YB 40:306-309, 1941

Beginning in October 1940, Dr. Tax spent eight months and Dr. Redfield five months in Guatemala resuming field work among peoples of the midwest highlands. In previous seasons Dr. Redfield had studied the mode of living of the Ladinos of the village of Agua Escondida, on the eastern side of Lake Atitlán. This year he devoted his attention to the San Antonio Indians, whose pueblo is the most important settlement in the municipio wherein Agua Escondida is but a recent hamlet of invading Ladinos. The materials obtained from the San Antonio Indians have two principal uses for the Institution's ethnological project. Combined with the data obtained from the Ladinos, they will make possible a monograph on the entire municipio community, which includes within it the three principal kinds of people living in the midwest highlands: Indians native to the municipio, invading Ladinos, and Indians who have moved into the municipio from other communities. It is proposed to describe the life of the municipio in terms of its bi-ethnic, or multi-ethnic, population, using ethnic differences, resemblances, and relationships as a general theme in terms of which to examine customs and institutions. It is expected that understanding will thus be increased of some of the basic features of midwest highland life: its commercialism, its secularism, and its general dependence on formal regulation and control. To this end Dr. Redfield visited almost every part of the municipio, and mapped the residences, and lines of communication in the most rural corners of the community as well as in the pueblo and hamlets themselves.

In the second place, the work with San Antonio Indians closed one link in a developing chain of comparisons. Previously we had knowledge of the customs of several Indian communities situated along the lake, of the Ladinos of Agua Escondida, and of the Indians of Chichicastenango to the north. But we did not know which elements of culture were to be attributed to Ladinos *per se* and which to local differences among Indians, differences which Ladinos might to some extent share. Now that we have knowledge of the Indians and Ladinos of the same municipio, distinction may be made with some confidence between local and ethnic culture variations, and at the same time one may begin to see where are to be found the

frontiers of diffusion and culture change, between Indian and Indian, and between Indian and Ladino.

Dr. Tax returned for his third field season at the village of Panajachel, with two main objectives: to obtain data needed to complete his monograph on the economics of the Indian community, and to determine the degree to which material on the mental life of individual Indians is representative of that of the whole community. For the second purpose, a sample of over 400 items of belief was tested on at least three, usually four or five, and sometimes more, selected Indians. Conclusions in this study, which will form the substance of a second monograph, are still to be worked out: In addition, some quite new information was obtained, and considerable work was done with informants never previously engaged. Noteworthy is a life history obtained from a middle-aged Indian with whom Dr. Tax was especially intimate.

Dr. Tax also devoted some time, with Sr. Juan Rosales, to the preparation of their report on the town of San Pedro, where Rosales did the field work. This report, of which some 200 typed pages are now ready, is being written in Spanish. Rosales spent most of the year in Sololá, writing the monograph, but he continued to collect material until the end of 1940. Since then, his chief contact with San Pedro has been through Sr. Agustín Pop, the Indian interpreter who has been writing a diary and collecting courthouse records for Rosales. In order to finish the report on San Pedro, which requires their constant collaboration and to obtain training that will add to his value, Rosales accompanied Tax to Chicago at the end of May for a stay of about a year, aided by funds of the Rockefeller Foundation.

Early in January was inaugurated the experiment in ethnographic method conducted by Mr. Benjamin Paul (Social Science Research Council Fellow) under the direction of Redfield and Tax. Mr. Paul is in San Pedro engaged in an independent study of the community for comparison with that of Rosales. Since Rosales kept a record of origins of his data, and Paul is doing the same, a comparison of information and conclusions may well yield very significant information for the study of field techniques.

Besides the work on selected communities, advances were achieved this year in extending and systematizing the more comprehensive study of all Indian Guatemala into which the community studies fit as special parts. Taking advantage of several years of experience in villages and towns of western Guatemala, Tax and Redfield developed, a schedule, on which may be quickly recorded a great many of the basic and readily comparable facts about local communities. As the municipios are both natural culture groups and also administrative units of the Guatemalan government, it is possible to use the municipio

as a unit of investigation, and to combine on a single schedule and program of survey both material taken from formal government records and information obtained orally from informants. In order to make the best use of the former class of material, Redfield and Tax first spent some time in Guatemala City and in offices of municipal government in order to understand the machinery of that government and the records in which its doings are set down. The resulting schedule passed through several stages of revision, and was worked out in municipios in the area where the principal field work has been done. It is 'now' ready for general systematic use in a survey of this part of Guatemala, or, indeed, for surveys in other parts of the country.

As one means of extending the general background of knowledge of Guatemala, and with the incidental objective of giving the schedule a further trial, Tax and Redfield made five-day trip of reconnaissance into eastern Guatemala. The itinerary included communities in the territory of the Pokoman and of the Chortí, and extended to Esquipulas, near the Honduran border. The trip resulted in a number of achievements. The worth of the schedule was demonstrated in San Pedro Pinula, where reliable and detailed information was obtained from municipal authorities in complete response to the schedule in less than two hours. Later in the afternoon and evening an excellent sampling of ethnographic data was obtained from an Indian family of the town. A very creditable paper on this municipio could be written from this single day of work. In the second place, confirmation was given to a hypothesis carried into the field (from a reading of Wisdom's report on the Chortí) that Chortí culture is more like that of Yucatán than it is like that of the western highlands of Guatemala. Furthermore, what was learned on this trip gave weight to the suggestion that the Indian societies of eastern Guatemala are more sacred and personal, and less formally institutionalized, than are those of the midwest highlands with which the project began. And, finally, there was discovered, or rediscovered, an excellent series of adjacent communities, between Guatemala City and the Pokoman villages, within which to study the progressive ladinoization, or de-Indianization, which is generally taking place in Guatemala.

In 1940 Dr. J. S. Lincoln received from the Carnegie Corporation a grant for ethnological studies among the Indians of the Nébj region in the Department of El Quiché, Guatemala, a group which has had relatively little contact with European culture. Dr. Lincoln's work, carried on under the auspices of the Division of Historical Research, proved so interesting that a small further grant was made by the Division for its continuance in 1941. Dr. Lincoln was engaged on this research

when he was taken seriously ill. He was brought with great difficulty over the mountains from Nébjaj to Sacapulas by Indian porters and by motor to Guatemala City, where he died on May 2, 1941.

Dr. Lincoln had completed an extremely thorough study of the calendar system now in use by the Indians of Nébjaj, showing it to retain many important elements of the ancient Maya of reckoning time. A manuscript embodying his findings was received shortly before his death, and will be made ready for the press. Dr. Lincoln's voluminous notes on social, religious, and political organization and material culture are being studied by Mrs. Lincoln with a view to their ultimate publication.

The untimely death of Dr. Andrade has, of course, halted field investigation of the Maya languages. As stated, in the introduction to this report, however, Mr. Bradshaw has been engaged to put in final shape for publication Dr. Andrade's almost completed monograph on Yucatec, a work in which are exemplified his remarkable abilities as a logician and as an analyst of primitive tongues. Attempt is also being made to arrange for the continuation of the research. That it should go on is most essential, not only for the light which it can shed on problems of Maya history, but also in order that the vast body of materials so meticulously recorded by Dr. Andrade may be augmented, and synthesized as a contribution to linguistic science in general. The first step must, of course, be a thorough study of those materials, in order to determine how they may best be utilized and to ascertain what additional field work be necessary. This stock-taking has been entrusted to Dr. Abraham Halpern of the University of Chicago. On receipt of his report, in about a year's time, it will be possible to give consideration to plans for the future.

8.12.

ROBERT REDFIELD, SOL TAX, AND
ALFONSO VILLA ROJAS

Social Anthropology and Linguistics

YB 41:273-275, 1942

The program in ethnology and social anthropology this year consisted of desk work rather than field enterprises. *The Folk Culture of Yucatán*, a book by Dr.

Redfield summarizing the results of the research carried on in Yucatán from 1931 to 1936, was published in July 1941. Dr. Tax completed his report on the economy of the Indian community of Panajachel. This will form the first of three volumes on that community. The other two volumes are in preparation: that dealing with the Indian world view is about half done; that concerned with the social organization is in its inception. Dr. Tax also wrote a short article on race relations in Guatemala, prepared a short manuscript—to remain unpublished until further developed—dealing with what appear to be important differences between highland and lowland Maya cultures, and organized materials on Middle American ethnology in connection with a course on that subject, which he and Dr. Redfield taught in the spring at the University of Chicago. At the end of the year, Dr. Tax left for Mexico City, where he was to teach a course in Maya ethnology, with special reference to ethnographic field techniques, at the Escuela Nacional de Antropología. It is his plan, following the termination of the course, to take a group of students to the Tzotzil community of Zinacantan in the state of Chiapas, to do field work in that little reported Maya group. For these purposes the services of Dr. Tax have been lent by the Carnegie Institution to the Escuela Nacional.

With the assistance of their class at the University of Chicago just mentioned, Dr. Tax and Dr. Redfield began a collection and comparison of material on Middle American ethnology which might ultimately become a contribution to a handbook on that subject. It is planned also to prepare a selected bibliography.

Sr. Alfonso Villa R. spent most of the year in revision of his manuscript on the Quintana Roo Maya, which is now ready for the press. In May, Villa reached the small Tzeltal community of Dzajalchen in the municipio of Oxchuc, near Tenejapa, in Chiapas, with the intention of remaining there several months carrying on a general ethnological study of these Indians, who had been the subject of a brief published report based on a reconnaissance of their villages made by Villa in 1938. His first report from the field contained maps and censuses of the community chosen for study and information on social organization. Of interest is the fact he reports that each settlement takes its name from a cave wherein is housed a cross at which members of that settlement perform their religious rites; each tract of land in the settlement is considered the permanent property of this cross; the son (never a daughter) inherits the land with obligation to keep up the prescribed rites, and sale of a tract does not change its belonging to the traditional cave.

Sr. Juan Rosales, field assistant to Dr. Tax, spent the year in Chicago, continuing the preparation of his monograph on the culture of the Maya of San Pedro de

La Laguna in midwest highlands of Guatemala. He was aided, by support from the Rockefeller Foundation. He has completed the introduction to his work, and the chapters on technology and material culture, comprising almost 500 typescript pages. He will remain in Chicago at least until January 1, 1943.

As was recorded in the preceding annual report, Benjamin Paul, a fellow of the Social Science Research Council, went to San Pedro de La Laguna to study the same community investigated by Rosales, as an experiment in ethnological method.

Mr. Paul spent a year in that village, and returned to the United States in December 1941. Having received funds from the University of Chicago to enable him to prepare his report, he set about this task at the beginning of the new year. Mrs. Paul, who accompanied him and did field work under provision made by the Committee for the Study of Dementia Praecox, Scottish Rite Fund, brought back unusual and interesting material on the socialization of the child.

A further contribution to the ethnological work of the Institution was made by the University of Chicago when it supplied a sum of money enabling Rachel Reese Sady to make a study of certain official Mexican records, with an evaluation of their usefulness to ethnologists. Mrs. Sady examined and, when necessary, transcribed or summarized the formal records made by national, state, and municipal governments pertaining to two communities known to contain a large Indian element but differing in most other respects. She then did enough field work in the first community (Ocotopac, in the state of Morelos) to enable her to form a judgment as to the extent to which conditions therein were reported in such records. The other community was one in Chiapas to which it is expected Dr. Tax will go in the winter of 1943. Mrs. Sady is writing a report which it is expected will be a guide, for the investigation of Mexican aboriginal communities, to students who may wish to take advantage of formal governmental records as a part of their work.

Beginning July 1, 1942, the program of field research will be strengthened as the result of an important addition to the Division staff. Through an arrangement with Duke University, Dr. John P. Gillin, of that university, has become a Research Associate of the Institution and a participant in its program of social anthropology and linguistics. Dr. Gillin is to spend the summer of 1942 initiating studies among the Pokoman of eastern Guatemala. This group, concerning which there is almost no information, was briefly visited by Dr. Redfield and Dr. Tax in 1941. Dr. Gillin has been informed as to the special interest this Maya group have for the general project, with regard to their critical position in connection with the supposed dichotomy of the Maya peoples. Into lowland and high-

land divisions, their interest for students of Indian-Ladino relations, and the possible interrelation of market systems, or their absence with other elements of Indian society. Dr. Gillin will, however, develop his research along such lines as seem most promising after his preliminary survey.

Melvin Marvin Tumin, a student of anthropology at Northwestern University, received a fellowship from the Social Science Research Council to enable him to acquire field experience in Middle American ethnology. This he will do in the eastern highlands of Guatemala, where his work will be supervised by Dr. Redfield.

While Mr. Samuel L. Bradshaw worked on the grammar of Yucatec left unfinished by Dr. Andrade at his death, Dr. Abraham M. Halpern continued the comparative study of other Maya languages. His initial task was to examine and organize Dr. Andrade's field notes and to review all published materials bearing on the linguistics of the Maya and their neighbors, with a view to estimating the present state of the study and recommending a course to be pursued in carrying it forward. In the year just ended, Dr. Halpern went through the notes and catalogued the phonograph record material. With the kind assistance of Mr. Edward F. Sywulka, a dictionary file was started for the Mam language. A beginning has also been made on a comparative dictionary file. The work was discontinued when Dr. Halpern took leave of absence as of April 1, 1942, in order to undertake studies of an Oriental language important in connection with the war effort.

8.13.

ROBERT REDFIELD AND ASSOCIATES *Social Anthropology*

YB 42:180-181, 1943

Dr. Tax spent most of the year in Mexico. From July through November he taught at the Escuela Nacional de Antropología; December and January he spent with nine students in the Tzotzil community of Zinacantan, Chiapas, instructing them in techniques of ethnographic field work. February he also devoted to this work, assisting the students in preparing a report on the work of the expedition. The next months, to the middle of June, were devoted chiefly to making last revisions of his manuscript on the economy of the In-

dians of Panajachel, Guatemala. While in Mexico, Dr. Tax began, with the cooperation, of the Escuela Nacional de Antropología and the collaboration of its cartographer, Sta. Rita López de Llergo, a large-scale language-density map of the Maya area. This map makes use of data from the original schedules of the 1940 Census of Mexico, furnished through the courtesy of the Department of Statistics of the Mexican Government, to spot the population, classified by language reported spoken, as accurately as possible. When the Mexican part is completed, it is hoped to extend the localization on the map to Guatemala, British Honduras, and the Republic of Honduras. As projected and begun, this map will be an improvement not only over previous linguistic maps of the area, but over population-density maps as well, since the population is spotted by the smallest local units. Sta. López de Llergo has adapted to cartographic purposes a decimal system of indicating the numbers of people.

Dr. Tax, while in Mexico was in contact with the group of linguistic missionaries from the Summer Institute of Linguistics. This organization has trained linguists stationed in many Indian communities in the country, including some in outlying Maya communities on which there is almost no ethnological information. Finding them eager to be of assistance, Dr. Tax took time to instruct many of them in methods of obtaining reliable ethnographic data.

The expedition to Zinacantán, although primarily a training enterprise for students of the Mexican Institute of Anthropology, furnished a considerable body of data on this hitherto unknown community. The whole Tzotzil group has been almost untouched by scientific research. In conjunction with the results of Sr. Villa's work among the Tzeltal, the results of the expedition give us a good start in understanding the ethnology and sociology of the Maya groups in Chiapas. The report of the expedition is still incomplete, but will probably be published in Mexico within a year. As a further result of this expedition and of Dr. Tax's teaching program in Mexico, a new research project, in which three of the students will return to the same region of Chiapas for six months each to work on problems of social anthropological interest, is under serious consideration. As planned, it will be financed cooperatively by the Instituto Nacional de Antropología e Historia, the State of Chiapas, and the University of Chicago, and will get under way in the autumn of 1943.

Sr. Rosales remained in Chicago until January, when he returned to Guatemala to continue the writing of his report on San Pedro La Laguna. Plans for publication of the first volume on the technology, in Guatemala are going forward while he is working on the chapters on the economy.

Sr. Alfonso Villa R. spent about 10 months studying Tzeltal communities (Dzajalchen, Yaxanal, and Tzuib). His wife accompanied him, and a field residence and "branch office" of the Institution was built in Dzajalchen. In spite of difficulties the absence of Indian men for periods of work on fincas, poor food, sickness, and the hostility of the Indians toward whites, Sr. Villa recorded excellent and abundant material. The institutions of these Indians include exogamous patrilinear groups, cross-cousin marriage, a dual division with ritual functions, and a remarkable form of witchcraft in which the sorcerer (in many cases) causes illness as a punishment for a sin committed by the sick person or a relative, and in which cure follows confession and illustrative whipping of the sinner, after divination, or diagnosis, by "pulse-takers." Villa will devote the summer and autumn to preparation of a report, and to giving a course in ethnological field method in the Escuela Nacional. His manuscript on *The Maya of East Central Quintana Roo* has been submitted for publication.

During the year plans to undertake a study of nutrition in Guatemala, to begin this summer, matured. Dr. Tax will direct the project, and the field work will be done by Srs. Antonio Goubaud Carrera and Juan Rosales. Sr. Goubaud, like Sr. Rosales, is a Guatemalan; this will be his first official connection with the Institution's program, although relations between him and members of the staff have been close since 1934 and he has spent the past years at the University of Chicago working partly under Dr. Redfield. In 1942 he participated in a nutrition study, jointly sponsored by the Office of Indian Affairs and the University of Chicago, in New Mexico. Plans call for study of the diet of both Indian and Ladino communities in every region of Guatemala.

During the summer of 1942 Dr. Gillin, under a cooperative arrangement with Duke University, engaged in a preliminary study of San Luis Jilotepeque, a Pokoman community of eastern Guatemala. Mr. Melvin Tumin then spent about nine months in the same community working especially on problems of acculturation and the relations of Indians and Ladinos. Supported by the Social Science Research Council, with collaboration of the Institution, he did his work under the direction of Drs. Redfield, Gillin, and Tax.

8.14.

ROBERT REDFIELD, SOL TAX, AND ASSOCIATES

Social Anthropology

YB 43:176–178, 1944

Because of duties connected with the war activities of the University of Chicago, Dr. Redfield was unable to take the field. He remained, however, in close touch with the ethnological work of the Division. The principal, undertaking of the period under review was a survey of the food consumption and food habits of the nonurban people of Guatemala. The project is designed to complement a similar study carried out some years ago by the Division in cooperation with the Nutrition Laboratory among Maya living under very different conditions, both of climate and of soil, in northern Yucatán.

By far, the most important of the manifold practical problems of human existence is that of filling the stomach. Men must be fed before any other activity can be undertaken. The quality and quantity of their food determines their health and vigor; the ease or difficulty of its attainment regulates the amount of effort they may put into activities beyond and above the mere business of keeping alive. Food supply, and physical environment interlock to produce the most cogent conditioning factors of any people's career. No anthropological or historical investigation can therefore strike very deep without taking them both seriously into account.

From the archaeological point of view, studies of food and cooking among the living Indians of Middle America are necessary in order to give us information on former times. This is needed to make clear the uses of utensils found in excavation. Of greater importance is knowledge of the nature and amount of food required by the ancients, in order to permit estimates of the number of people who could have supported in various sorts of country. That modern data will be, so to speak, retroactively reliable is indicated by the strong conservatism of the Maya in other regards as, for example, in clothing, in agricultural practices, and in house building. And for present-day needs the survey will furnish basic data on the food of the country as a whole for comparison with that of other countries and regions and for determining the nutritional factors in problems of public health in Guatemala; as well as for comparisons of foods consumed in different type of Guatemalan communities in order to weigh the geographic, agronomic, economic, and cultural factors involved in such differences.

Plans for the survey were drawn in August 1943 following a conference in Guatemala City between Dr. Tax and Srs. Goubaud and Rosales, and field work was begun the next month by Srs. Goubaud and Rosales and Sr. Agustin Pop, a young Guatemalan who has been Sr. Rosales' assistant in San Pedro La Laguna.

Since the attempt is to determine the kinds and quantities of food consumed, with little or no immediate reference to causes and effects, or to the chemical composition of the foodstuffs, the data that are being collected are limited to detailed records of the daily consumption of individuals of sample families, to recipes (to make the consumption records exact and intelligible), to information on kitchens and utensils and customs relating to food, and to a general index of foodstuffs used throughout the year, with information on prices, seasonal variations, etc.

Considerable attention is paid to obtaining a scientific sampling of families for study within each community. The importance of getting an adequate cross section made it advisable to choose, so far as possible, communities in which ethnological studies have already been made, so that the economic and social distinctions that must be taken into account can be known without further extensive work. In regions where no such investigations have been undertaken, more time was allotted for the survey. Otherwise, the communities were chosen to represent regional, geographical, cultural, and social differences in the country as a whole.

By the end of June, Sr. Goubaud had completed work in five communities: those of Ladinos and Indians in San Luis Jilotepeque (Pokoman) and Jocotán (Chortí) in eastern Guatemala, and in the coffee plantation "Nueva Granada" in the southwest extremity of the country, where the Indians are largely of Mam origin. Simultaneously, Srs. Rosales and Pop completed studies in another five communities, all in Central Guatemala: the highland Indian towns of San Pedro La Laguna (Tzutujil) and Panajachel (Cakchiquel), the Ladino communities of Sololá and Agua Escondida, and the lowland colony of San Pedro Indians in the village of Cutzan. By the end of 1944 Sr. Goubaud is scheduled to finish work on the Indians of San Miguel Chicaj (the easternmost Quiché town, in Baja Verapaz) and on the Indians and Ladinos of San Juan Chamelco (a Kekchí town of Alta Verapaz). In the same period Srs. Rosales and Pop will study in Aguacatán (southeastern Huehuetenango), where there appear to be two possibly distinct Indian groups as well as a settlement of Ladinos, and in the Mam Indian town of Santiago Chimaltenango (western Huehuetenango); if they have time, they will also collect food data in Santa Eulalia, a Chuj town in northern Huehuetenango.

Field studies will be finished by the end of 1944, and during the first months of 1945, Sr. Goubaud will compile and correlate the data and draw conclusions. Sr. Rosales, meanwhile, can return to his report on the culture of San Pedro, work on which was suspended to permit his participation in the food survey.

Partly to choose communities to be studied in the food survey, partly to obtain first-hand knowledge of northern Guatemala, a month's reconnaissance of Huehuetenango, northern Quiché, and Verapaz was undertaken in April. Dr. Tax entered Guatemala from Chiapas at the extreme northwest corner of Huehuetenango, where Srs. Goubaud and Rosales met him. Together, by horseback and automobile, they then traveled across the whole of northern Guatemala almost to the Lago de Izabal, stopping on the way in about 40 communities. Besides obtaining a general idea of the geography and sociology of the area, for comparison with that to the south, they were able to trace the changing religious complexes and other cultural differences by fixing attention upon a small number of specific cultural traits.

Work in Chiapas made great strides during the year. It has been mentioned that Sr. Villa completed a second season in Oxchuc, this time accompanied by four students. In addition, three of the students who last year were trained in Zinacantán by Dr. Tax, returned to Chiapas in December 19 after six months' field work in the region. Sra. Calixta Guiteras Holmes, whose special interest was the family and clan organization, worked especially in San Pedro Chenalhó (Tzotzil) and in Cancuc (Tzeltal); Sr. Ricardo Pozas Arciniegas, specializing on the economy, studied chiefly in Chamula (Tzotzil) and Huistan (Tzeltal) and Sr. Fernando Camara Barbachano worked in Tenejapa (Tzeltal), and San Miguel Mitontik (Tzotzil), especially on the politico-religious organization. Funds for their work were supplied equally by the Instituto Nacional de Antropología e Historia (Mexico), the state of Chiapas, and the University of Chicago, but the project was consummated under the direction of Dr. Tax, with advice from Dr. Redfield and Sr. Villa. Sr. Villa had numerous contacts with the three field workers. Dr. Tax directed the work by correspondence, and before making the reconnaissance of Guatemala, in April, he spent a week in Chiapas in consultation with Sra. Guiteras and Srs. Pozas and Camara.

As a result, comparatively full information about the whole highland Tzeltal-Tzotzil region of Chiapas is now at hand; during the next year the field notes will probably be organized and one can expect that for the first time real understanding of the ethnology, sociology, and economy of this hitherto unknown region will emerge. Indeed, within the space of two years we have probably obtained as much information about

this area as there is available about any similar area in all of Middle America. The region appears to be of extraordinary importance ethnologically, with a social organization of a type more primitive than any hitherto encountered, in Middle America.

To facilitate the elaboration of all the materials collected in Guatemala and Chiapas during the past 10 years, both by members of the Instituto staff and by others, a project to microfilm manuscript material, which can then serve as a basis for specialized publications, has been inaugurated. It is hoped to gain the cooperation of institutions and individuals that possess unpublished materials on Middle American ethnology, social anthropology and linguistics, in order to obtain a complete library of microfilmed materials that can be used by all concerned. Plans already under way include the microfilming of a large body of manuscript materials; Mr. Melvin Tumin is assisting with the editorial work. The more difficult problem is that of obtaining means to index all the materials to make them easily usable by scholars in the field. If the project comes to fruition, it will solve the dilemma posed by the practical impossibility of publishing all field data collected, on the one hand, and on the other the desirability of publishing conclusions and interpretations without making available the material on which they are based.

8.15.

ROBERT REDFIELD AND ASSOCIATES
Social Anthropological Research

YB 44:173-177, 1945

No notable single accomplishment marked the advance made in social anthropological research of the Division during the past year; no outstanding discovery in the field is to be reported; and no new unit of investigation was begun. The members of the group were engaged in terminal or transitional activities. Dr. Redfield made a short visit to Yucatán and to Guatemala; in Yucatán he reviewed the circumstances that would attend a proposed restudy of Chan Kom, one of the Yucatecan communities studied a decade ago; and in Guatemala he carried forward, in consultation with members of the staff and with representatives of the new government of the Republic, various pieces of

business incidental to the Division's research program in that country. Dr. Tax's time was borrowed in large part by the University of Chicago; nevertheless, for Carnegie Institution he brought nearer completion a non-technical book on the Indian culture of Panajachel. Sr. Antonio Goubaud concluded a period of special employment, and completed a monograph containing the results of the study of diet in rural Guatemalan communities which he carried on in the field in 1944 with the assistance of Sr. Juan Rosales and Sr. Agustin Pop. Sr. Alfonso Villa Rojas prepared for microfilm reproduction his extensive notes on Tzeltal communities of Chiapas, and in June came to Chicago to write comparative monographs. The publication, during the year, of Sr. Villa's book, *The Maya of East Central Quintana Roo*, provides the student with the last expected monograph resulting from the Yucatán project, the first of the two research programs carried on by this group of workers, and so brings this first project to a close, while the Guatemalan project is still in progress.

The brevity of this annual report provides opportunity here to review what has been done during the past 15 years.

By 1930 the Institution had already for many years been carrying on researches in Maya archaeology. In that year, there was initiated a new program in which problems of the Maya area were to be attacked by specialists representing many kinds of scientific interest. Ethnology was included, and Dr. Redfield formed a plan to study the living people of Yucatán. Because the Maya of Yucatán are all much the same in language and in native custom, a project was proposed, and carried out, to investigate four communities chosen to represent different degrees of exposure to modern urban influence. The project was so conceived as to serve two interests: that in the ethnography of the Maya, and that in the effects of contact with modern civilization of simpler and more isolated societies. The program was realized in every particular except that a promised publication on the city of Mérida was not produced. There were published: a monograph on a peasant village (Redfield and Villa Rojas 1934); another on a tribal community (Villa Rojas 1945); publications on a town of mixed population and marginal in character to village and city (M. Redfield 1935; R. Redfield and M. Redfield 1940); and, in 1941, a summary and concluding volume expressing the more general conclusions of the study (*The Folk Culture of Yucatán*, University of Chicago Press).

This project had the following principal results. Sources of information on the present-day Yucatec Maya were provided that exceed in both quantity and quality everything else on the subject that had previously appeared or has since been published. The eth-

nography of the region was assembled in a single synthesis, in *The Folk Culture of Yucatán*. The student of Maya history was provided with a full account of the present-day pagan cult, including texts of prayers. It was fairly well established that the culture of Quintana Roo is a reintegration of elements of custom both pagan and Christian, and it was shown that processes of culture growth which move toward consistency operate indifferently on European and on Indian elements. From ethnographic facts almost exclusively, a historical hypothesis was offered as to the course of development of conventional attitudes between racial groups and status groups in the peninsula. For what was probably the first time, a study of a regional American Indian field was (virtually) opened with a project directed by concepts and questions of general interest to students of society and of social change and was carried through to completion. Conceptions and hypotheses as to the natural association of certain characteristics of human living in isolated folk societies, formed by earlier writers, were restated and clarified, and the power of these ideas to guide the acquisition of new knowledge was demonstrated in terms of a large body of well reported fact. A number of general propositions as to society and its changes were enunciated and given some support from this body of fact. Interdependence between heterogeneity of population and the secularization of life was demonstrated for this case, and it was shown that in Yucatán religion has tended to pass over into magic. The role of sorcery in expressing the insecurity of a member of a disintegrated society was strongly suggested. These are some of the many conclusions of general interest which were reached.

While the Yucatán project was still in progress, the work of this group was extended into the western highlands of Guatemala, then into the adjoining highlands of Chiapas, and finally into the eastern highlands of Guatemala, so that all parts of America occupied by Maya-speaking peoples, save the Huastec area of northeastern Mexico, were included in the field of study. In the development of the Guatemalan investigation, the principal part has been played by Dr. Tax. Beginning in 1934 with Santo Tomas Chichicastenango, Dr. Tax, with or without associates, studied Cakchiquel or Tzutujil communities on Lake Atitlán, and made briefer studies of Chortí, Pokomam, and Mam communities in Guatemala, and of Tzotzil communities in Chiapas. To Alfonso Villa fell the task of making studies, of long duration and intensity, of the difficult Tzeltal Indians of Chiapas. In 1942 Dr. John Gillin, of Duke University, became associated with the ethnological program of the Institution, making observations on Pokomam communities in eastern Guatemala. His work there was supplemented by that of Dr.

Melvin M. Tumin. Dr. Gillin extended his research to a non-Maya people, Xinca of Guazacapan, Guatemala.

The extraordinarily diverse local variations of culture in Guatemala made impossible any such single theme of investigation as had been possible in the relatively uniform Indian country of Yucatán. Dr. Tax accordingly devised and put into effect methods for representative sampling of the area included, and for making verifiable and comparable the reports of the several investigators. In 1934 the municipio was identified as the basic unit of study, and principal types of municipios were recognized. In succeeding years outlines were prepared to guide the junior investigators; a survey of eastern Guatemala was made by Drs. Redfield and Tax in which a schedule was worked out for the quick reporting of certain information according to municipios; the preparation of community maps was systematized; a method for comparing local cultures quickly according to sample elements of belief and custom was tested; and a project for the preparation of field notes in more or less uniform manner for microfilm reproduction and general distribution among all research students of the area was put into effect.

The problems guiding the later stages of investigation were developed in the course of the ethnographic exploration. These problems are in part ethnological, in part historical. Dr. Tax is determining the distribution of the principal ethnographic types among the Maya peoples, and is bringing this descriptive classification into comparison with linguistic classifications offered by students of Maya languages. Identification is being made of regions in which certain elements of culture (calendar, pagan fertility rituals, sorcery, and nahualism) are strongly emphasized, as compared with other areas in which these elements are absent or unimportant. Problems of much general or sociological significance are receiving great attention. The conclusions reached in Yucatán as to the interdependence of individualization and secularization with loss of isolation and homogeneity have been tested and revised in the light of facts from Guatemala. The west highland communities of Guatemala have been recognized as providing an exceptional and important societal type: highly commercial and individualized societies with local cultures and with people maintaining a primitive world view. The lack of dependence of secularization upon technological revolution has been brought to the attention of those who have studied secularization from the history of western Europe alone. Dr. Tax has completed a monograph in which for the first time the economy of a nonliterate farming and trading people has been reported with the facts and figures of cost accounting. He has also written monographs on other aspects of the Indian culture of

Panajachel, and monographs by other investigators on Tzutujil, Pokomam, Tzotzil, and Tzeltal communities are in preparation.

The studies described above have contributed significantly to the development of social anthropology in Mexico and in Guatemala. It may be claimed that 15 years ago this sort of research was entirely unrepresented in these two countries, that it, is now being effectively carried on in both by their own citizens, and that the work of the Carnegie Institution group has been the chief instrument of this change. Soon after its publication in English, *The Folk Culture of Yucatán* was issued in Spanish translation; a Portuguese edition is now under discussion. In 1942 Dr. Tax taught for a semester in the National School of Anthropology of Mexico, and then took to Chiapas a group of Mexican students whom he trained in field methods. Certain of these students then continued field research without direct guidance. In 1943 Alfonso Villa taught in the School, and he too supervised the work of Mexican students in the field. Villa himself had been brought to the United States in 1933 to study anthropology at the University of Chicago. He was followed by Antonio Goubaud of Guatemala. Later Juan Rosales, whose gifts as a field investigator had been discovered by Dr. Manuel Andrade, was also brought to the United States for training; after returning to Guatemala he was sent by the government of that country to the School in Mexico for thorough preparation as an anthropologist.

The Division's work in social anthropology has included many activities marginal to the main lines of investigation, and has drawn within its program many enterprises carried on under auspices other than those of Carnegie Institution. In 1939 Villa participated in a study of the Tarascan Indian carried on for the Mexican government. The work of Sr. Julio de la Fuente in Oaxaca was done partly under the influence of the Carnegie group, and in 1943–44 he came to Chicago to write under its guidance. In 1944 and 1945 the Institution carried out a study of diet of rural Guatemalans; the results will be published by the government of Guatemala. The students of Drs. Redfield and Tax at the University of Chicago have written monographs on subjects of Middle American anthropology and social anthropology; these papers are in substance contributions to the program of the Institution; they include works on the following topics: the mayor-domia, the concept of the evil eye, collective and cooperative labor, godparenthood and related institutions, the relations between Indians and Ladinos. Two fellows of the Social Science Research Council have carried on field research in the Maya area under direction of Drs. Redfield, Tax, and Tumin. There have been edited and prepared for publication half a dozen manuscripts

on Middle American ethnology written by persons outside the staff of the Institution. Two of these may especially be mentioned: Charles Wisdom's *The Chortí Indians of Guatemala* [University of Chicago Press, 1940], and Oliver La Farge's *Santa Eulalia* [University of Chicago Press, 1947]. Finally, it may be mentioned that the very considerable expansion of the program of research on the living Maya has been accomplished without corresponding increase in the budget provided by the Institution. The work has been aided by contributions from other sources, including the Viking Fund, the Rockefeller Foundation, the University of Chicago, Duke University, the Social Science Research Council, the National Institute of Anthropology and History of Mexico, and the government of the Mexican state of Chiapas.

8.16.

ROBERT REDFIELD AND ASSOCIATES *Social Anthropological Research*

YB 45:215–217, 1946

The activities of the group working in this field during the period under review took the form, for the most part, of publication or of preparation of manuscripts for publication. A principal exception was the work accomplished by Dr. John Gillin of Duke University, who returned in the summer of 1946 to San Luis Jilotepeque, in eastern Guatemala, to resume his studies of the Chortí. He has taken with him Mr. William Davidson, a student who will make personality studies among the Indians. In March, Calixta Guiteras Holmes returned to Chiapas, Mexico, to continue work in the area, and especially in the hitherto unstudied Tzotzil town of San Pablo Chalchihuitán. Ricardo Pozas Arciniegas also returned to Chiapas to continue his study, especially of Chamula, during the months of December 1945 and January 1946. These Mexican field investigations are under the direction of Dr. Tax.

Dr. Tax, while devoting half his time to teaching at the University of Chicago, carried forward various research and publication projects. In the autumn of 1945, he delivered a series of eight lectures on, the Indian cultures of highland Guatemala, the materials of which constitute a part of his book on the Panajachel Indian community. During the summer of 1946 he will devote

most of his time to completion of that work, which should be ready for publication by the end of the year.

During the year the first series of eight manuscripts of the *Microfilm Collection of Manuscripts on Middle American Cultural Anthropology* was published and distributed. Although the University of Chicago Library is actually publishing the series, and funds for editing the manuscripts were supplied by the Viking Fund, this microfilm project had its origin in the ethnological work of Carnegie Institution. Under the editorship of Dr. Tax, who consulted with Dr. Alfonso Caso in the inception of the project, there has been created a continuing library of ethnological and linguistic material which any individual or institution can buy as a series of books. This form of publication brings into quick circulation among scholars the results of field work in relatively unelaborated form, so that specialists may study not only the investigator's conclusions, but also the primary data, and may do so without having to wait for more formal publication. The project is also designed to improve methods of research. In some other sciences, the report of the results of an experiment can be verified by repeating the experiment; but field research in the social sciences cannot usually be repeated. The scholar must therefore, in most cases, accept or reject interpretations and conclusions on the basis of what the field worker chooses to publish. The printing of all field materials in as nearly their original form as possible is impracticable; not only is it costly, but since only a few specialists would ever read the original materials, it is wasteful. Thus, the reporter publishes only what he judges is pertinent to his thesis, and the reader must take on faith the writer's competence to present a fair account. But now the *Microfilm Collection* makes available the full field observations, even though in their original rough form.

All eight of the items of the first series now published contain notes on investigations in which the Institution has had a hand. They include J. S. Lincoln's posthumous report on the study of the Ixil Indians, which was partly financed through the Institution; Melvin M. Tumin's study of San Luis Jilotepeque, which was done with the advice of the Institution staff; Dr. Redfield's notes on Agua Escondida and on San Antonio Palopó; Mr. Villa's notes on Oxchuc; and three of the studies resulting from the Chiapas expeditions directed by Dr. Tax, two by Fernando Cámara Barbachano and one by Calixta Guiteras Holmes.

The response to the *Microfilm Collection* on the part of other research institutions and libraries has exceeded expectations. Within a few weeks after the preliminary announcement, more than a dozen subscriptions had been received.

Mr. Villa began the large task of writing up the results of the studies of the Tzeltal and Tzotzil Indians

which he has carried on for several years. To do this he came to Chicago and remained there during the year. He first studied and annotated the great body of ethnographic materials at the University of Chicago (over 6,000 pages), which were obtained from Indians of these two groups by students who worked under Dr. Tax. This done, he began the preparation of a book that will present the life of the Tzeltal community of Oxchuc and, with this as the central point of reference, the comparative ethnology of the entire Tzeltal-Tzotzil area of Chiapas.

Mr. Villa's work was interrupted by an accident in which his leg was broken, but two chapters and certain tables and maps were finished. In the course of his study, he became especially interested in problems of kinship terminology and practice and began work on a special monograph on this subject. Restudy of the kinship system characterizing the ancient Maya, and those of the Lacandones, the Tzeltal, and the Tzotzil of ancient times, led him to the conclusion that the systems of totemic clans found among the Lacandones is but a local variant of a social and kinship system derived from a system general in the Maya area in pre-Hispanic times and represented also in the communities recently studied in the field by Mr. Villa. The development of this investigation should clarify our understanding of the form of social structure which anciently prevailed among the Maya.

During the year the results of the food survey of Guatemala, which was conducted by Srs. Goubaud, Rosales, and Pop under the direction of Dr. Tax in 1943-45, were put in manuscript form. They are to be published by the new National Indian Institute of Guatemala, of which Mr. Goubaud is the director.

Also during the year, Sr. Rosales, who is now studying in Mexico City while continuing his work for the Institution on part time, completed his second volume on San Pedro La Laguna. The first volume, on the technology of the community, is being prepared for publication by the National Indian Institute, which will probably also publish the subsequent volumes. The second, on the economy of San Pedro, was prepared by Sr. Rosales with the assistance of Sr. Julio de la Fuente, the Mexican anthropologist, who, it is expected, will continue to collaborate with Sr. Rosales in subsequent volumes. The third will contain an account of the social organization of the community, including the familial, local, political, and religious organizations; the fourth will be a study of social control, and will include the large body of court records obtained over several years in San Pedro. The last volume will be a statement of the mental life, the folklore, and beliefs of the Indians.

The manuscript of Mr. Oliver LaFarge on the Indians of Santa Eulalia was edited for publication under

the direction of the Institution staff and Dr. Melvin M. Tumin. It is being published by the University of Chicago Press.

8.17.

ROBERT WAUCHOPE

House-Type Studies in Yucatán

YB 33:100-101, 1934

The spectacular religious structures of the Maya have to date almost monopolized the attention of archaeologists. Furthermore, the living quarters of the pre-Columbian Maya, with the possible exception of the so-called "Palaces," were built of perishable materials and are now represented only by the low mounds upon which many of them seem to have been built. Because of their inconspicuousness and because they yield little in the way of specimens, few of these mounds have been excavated. The result is that we know next to nothing of the ancient dwellings, nor of the objects made and used by the common people. Our picture of Maya life is thus very one-sided. Also, lack of precise information regarding the real meaning of the house mounds prevents interpretation of the significance of their distribution and judgment as to the very important question of whether the Maya "cities," as represented by the temple-groups, were actually urban communities or whether they were merely ceremonial and market centers.

Investigation of the location and number of house mounds in a given area at Uaxactún by Mr. Smith [Chapter 28.10], and subsequent excavation of some of them by Mr. Wauchope [Chapter 1.19] indicated the great possibilities of research upon these hitherto largely neglected remains. Mr. Wauchope's digging, however, revealed many archaeological features, such as post holes, ash-beds, etc., which were not understandable because so little was known of the structure and interior arrangements of the houses which had stood upon the mounds. It therefore seemed best, before making further excavations, to attack the problem, so to speak, from the other end by studying modern Maya houses which, according to historical accounts and a few fresco representations, are similar to those of ancient times. It was thought that if we knew how the present-day domiciles were located, how they were built and

how furnished, and if we could determine how they disintegrated, valuable clues might be provided for future archaeological work. And quite aside from its archaeological implications, a thorough comparative study of domestic architecture among the various Maya groups is needed for ethnographic purposes.

Mr. Wauchope accordingly reviewed the archaeological literature on house mounds and that bearing on houses of the early historic period and of the modern tribes. In the winter and spring of 1934 he began his field survey in Yucatán. From Chichén Itzá as a base, trips were made to the neighboring towns of Pisté, Xocenpich and Dzitas to the north, and Nictenhá, Ticimul and Chan Kom to the south; to Valladolid and some of its neighboring towns, Chichimila, Tikuch and Yalkom; to Tizimín toward the northeast; to Temax and Dzilam González, Motul and Telchac in the north; to Mérida, Chicxulub and Hunucmá in the northwest; to Izamal and Sotutá in the central part of the state; to Muna, Ticul and the neighboring settlements of Tab and Sabachché to the southwest; to Peto in the south and to Catmis, Tzuiche and Lake Chichankanab farther south (in the former state of Quintana Roo); to Campeche, China and Huayamon in northwest Campeche; and farther southeast by boat from Campeche to Champotón. The east and northeast coasts were visited, but information concerning the houses in these regions is being sought from other people who have had occasion to see them.

A minute study of every detail of house construction was made, with especial reference to the manner in which abandoned houses fall to pieces and to the nature of the traces left by various house features after all perishable materials have disappeared. In addition, the results of fire and hurricane were recorded, so that indications of these destructive agencies may be recognized in future excavations. The investigation also included other types of structures associated with dwellings: boundary walls, kitchens, storehouses, beehive shelters, ovens, steam baths, tanneries, water sources, milpa shelters and corn bins. The interior arrangement of the house and its furniture was recorded, especially those things which might leave traces in ruined houses; fireplaces, household pottery, manos and metates, implanted metate and storage tables; wash troughs and ash heaps.

Expecting that traces of the various features mentioned above will some be found in ancient house sites, Mr. Wauchope also made note of their social implications so that by comparison or contrast something of the former life of the common people might possibly be deduced.

One of the more puzzling historical problems that was encountered, and with some archaeological significance, was that of the rounded ends which, in

Yucatán, are almost invariably added to a basically rectangular house framework. All the houses excavated at Uaxactún were rectangular in plan, but believing that the ancient Yucatecan houses must have had rounded ends, Mr. Wauchope spent two days in the environs of Chichén Itzá examining examples of what may have been the ancient house sites of that city. Unlike the house sites at Uaxactún, these were not entirely covered by mounds, and walls could be traced by clearing away the surface underbrush and vines. But every one of the 13 sites so examined seemed to be rectangular. So superficial an examination can not yield positive evidence that the ancient Chichén houses were all rectangular, but this seems probable, for none of the frescoes shows recognizably rounded ends of the modern type.

At the close of the period under review in the present report Mr. Wauchope had finished his work in Yucatán and had begun a similar study in the highlands of Guatemala.

8.18.

ROBERT WAUCHOPE

House-Type Studies in Guatemala

YB 34:128–129, 1935

The study of modern Indian house types, initiated in Yucatán and Campeche during the months of February to June 1934, was continued Guatemala until the middle of August.¹

Houses were investigated in the non-Indian lowland settlements from Puerto Barrios southwest to Quiriguá; in the semi-arid and semi-mountainous country from Zacapa south to Chiquimula, San Esteban and Elena, then east to San Juan Ermita and north to Jocotán, near the Honduran border; in the highlands from Guatemala City west to the Lake Atitlán villages, to Quezaltenango and San Pedro Sacatepéquez, and north west to Chichicastenango, Santa Cruz del Quiché, Huehuetenango, and Chiantla. On the return to Guatemala City two days were spent at Santa Apolonia and Tecpán. A week's stay was made in the Alta Verapaz at San Juan Chamelco, Cobán and San Cristóbal, the Baja Verapaz being observed on the return trip south to San Agustín on the railroad. From Guatemala City the railroad was followed west to

Retalhuleu and its neighboring Cakchiquel town, San Sebastián; then northwest to the Mexican border at Ayutla. The final trip was to Cuilapa, southeast of Guatemala City. The Petén had already been visited by Mr. Wauchope in 1932.

Besides making a detailed study of actual house construction, Mr. Wauchope recorded the way in which abandoned houses fell to pieces and what clues to the nature of their perishable superstructures remained on sites where the framings themselves had disappeared. The geographic distribution of variable features, such as ground-plans, was recorded an information as to the relative antiquity of these variations was obtain whenever possible. Word lists of the names of various parts of the houses were collected in Chortí, Quiché, Cakchiquel, Tzutujil, Mam, Jacalteco, Kekchí and Pokonchí. Attention was also directed to house furnishings, to surrounding property, and to the social significance of boundary walls and of the allocation of space within the house itself. Any related items of sociological, religious or psychological interest were also noted.

The Guatemalan house was built on the same fundamental structural plan as the Yucatecan house. Practically the only differences between houses of the two areas were minor. In Guatemala, for example, wall plates rested in the forks of the main posts; in Yucatán they were carried by cross-beams which rested in the main post forks. In Guatemala the pole plate was usually a large and additional member of the house framing, and, distinct from the wall plate, it was carried by cross-beams; in Yucatán the same timber often served in both capacities, or if distinct the wall plate was much smaller and lashed to the under side of the common rafters. Again, Guatemalan main rafters were not always forked like their Yucatecan counterparts, and were footed differently to the nuclear house framing.

The wide-spread use of adobe brick wall masonry and of adobe mud daubed over a cane or light wooden wall framing was another point of difference between the houses of the two countries, for Yucatecan "bush house" walls, with a few exceptions, were built of heavy vertical wall poles, or of light wattle (both horizontal and vertical), or of dry rubble masonry.

The outstanding difference, however, was that of ground-plan. Guatemalan houses were invariably either square or rectangular, but in Yucatán there were no square houses at all and rectangular houses were distinctly localized in their sparse geographical distribution, being in most cases correlated with non-Indian populations. The characteristic apsidal house of Yucatán

was entirely absent in Guatemala. There was some hearsay evidence in Guatemala that the square house plan and the resulting pyramidal roof were older and possibly more nearly aboriginal forms than the rectangular houses with longer ridgepoles. This evidence was corroborated to a certain degree by a correlation of these forms with those the more isolated, purer-Indian populations, such as those of Santiago Atitlán, San Pedro de Laguna, San Lucas Toliman, San Sebastián and Santa Apolonia.

Throughout the investigations, comparison with or contrast to the ancient house types excavated at Uaxactún, Guatemala, and examined in the environs Chichén Itzá, Yucatán, was kept in mind. Platform substructures, terraces, ground-plans and household furnishings were the outstanding possibilities for this phase of the study.

Data for further investigation of the "temple prototype" theories were collected, this subject to be discussed in full in a forthcoming publication on the season's work.

The word-lists present some interesting subjects in linguistics. The wide-spread distribution of words having similar literal translations in many languages was significant; "Mouth of the house" for "door," "road of the rat" for "roof purlin," and "leg of the house" for "main post" are examples. The almost complete displacement of an aboriginal word for "main rafter" by the Spanish word *tijera* (scissors) or some Indian corruption of this word, as wide-spread, not only in Guatemala but in Yucatán also. Mr. Wauchope is at present going through early Indian dictionaries and relaciones in the hope of finding linguistic solutions to some of the historical problems arising from the seasons work. Whether or not, for instance, the rounded ends of Yucatecan houses are aboriginal or are intrusions from another area may be revealed by the finding of a sixteenth century Indian word for some part of the house essential to this type of house-plan. Many early Spanish records are also being searched for any references to the Indian dwellings of those times.

Mr. Wauchope hopes that future investigators in the Maya field will help in this survey by observing the native dwellings of any areas unrecorded for house types, with especial reference to substructures, ground-plans and wall construction.

NOTES

1. The purpose of the house-type survey is explained in [Chapter 8.17].

9.0. ETHNOHISTORY

9.1.

FRANCE V. SCHOLES

History of Yucatán

YB 30:155–157, 1931

Historical studies, as a part of the general Yucatán Project, have not advanced beyond the preliminary stage. A statement of the general problem and a brief outline of some of its special phases must, therefore, take the place of a report of actual research.

The history of Yucatán from the period of the Spanish Conquest to the present time has a definite importance not only in relation to other phases of the Yucatán Project, but also for the general field of Latin American history. The significant problems of the history of those Latin American countries where the Indian has survived in any considerable numbers are essentially social problems. Latin America may be regarded as a laboratory in which vast experiments cultural and sociological in character have been carried out. Aboriginal civilizations, varying in achievement, flourished over a period of many centuries in several parts the Latin American area. In the sixteenth century these civilizations were submitted to a rude shock with the conquest of America by European races, but neither the Indian nor his culture was wholly destroyed. The

Indian survived, and today Indian blood, pure or mixed with European or Negro blood, is the predominant strain in the population of many Latin American countries. Elements of aboriginal culture also survived, either in the form of imposing ruins, which are witnesses of former achievement, or in living culture elements such as language and old folkways. To these living Indian elements have been added many characteristics of Hispanic culture. The four centuries since the Conquest have been characterized, then, by a long process of culture fusion, conflict and amalgamation, resulting in the evolution of a Hispano-Indian civilization, varying in type depending upon geographic conditions, the virility of the old Indian culture, and the policies and prowess of the conquering race. The survival of the Indian and of phases of his culture, fused with and modified by European elements, is the basis of many of the major modern Latin American problems of political and social significance, such as the distribution of wealth, land tenure, general economic progress, education and public health. In recent

years, moreover, the art and literature of Latin America, especially of Mexico, have been vitally affected by the same influences. The study of Latin American history is, therefore, essentially a study of the fusion and conflict of cultures. A sympathetic understanding of these processes of social and cultural evolution is essential in any just estimate of contemporary Latin American politics.

The history of Yucatán from the time of Conquest to the present offers an important opportunity for study and research in these processes of historical social evolution in Latin America. The aboriginal civilization of Yucatán was virile and highly developed in its several aspects, architecture, religious ceremonial and priestly learning. The modern population of Yucatán is still largely Indian, and, although present-day conditions of culture vary from an urban, partially industrialized center, such as Mérida, to the outlying, inland villages of the bush, there is a large content of Indian influence and old native folkways present everywhere. The archaeologist studies the aboriginal civilization as it existed in the centuries preceding the Spanish Conquest. The ethnologist describes modern village and city life and folkways. Studies in Yucatecan history, beginning with establishment of Spanish domination and reaching down to recent times should tie together and give unity to the researches of the archaeologist and the ethnologist, as well as serve as a notable chapter in the general comprehensive story of the evolution of a Hispano-Indian civilization in Latin America. Such is the general thesis which will determine the character of historical research as a part of the Yucatán project. A brief outline of some of the more important special problems to be studied as aspects of the general process of social change in Yucatán follows:

1. The character of the military conquest of Yucatán by the Spanish monarchy in the sixteenth century.
2. A description and estimate of the Spanish civilization introduced into Yucatán subsequent to the Conquest, with reference especially to: a. the general scheme of government introduced in the Indies and the social and political principles to which it gave expression; b. the character of local provincial administration and justice in Yucatán; c. ecclesiastical organization; d. relations of church and state; and e. the counter-influence of Indian customs in Spanish life.
3. The legal, economic and social position of the Indian under the new regime: a. Spanish Indian policy and its practical application in Yucatán, with special reference to the *encomienda* and the exploitation of Indian labor; b. Changes wrought in the distribution and amount of Indian population; c. land tenure and village organization under the new conditions; d. the policy of Spain with regard to race fusion and actual conditions of fusion in Yucatán.

4. The influence of the Church on aboriginal life: a. organization of the missions; b. methods employed in converting the Indian; c. influence of the Church in destroying the old aboriginal ceremonial; d. the Church as protector or exploiter of the Indian; e. general estimate of the permanent character of the conversion of the Indian; f. evidences of the fusion of Christian and pagan rites.
5. Economic life and material culture in post-conquest Yucatán, with especial reference to the introduction of new foodstuffs, tools, clothing and to changes wrought in agriculture.
6. The intellectual life of the Hispano-Indian community: a. schools and general intellectual activity; b. problems of language and the study of native linguistics; c. the role of the civil government and the Church in preserving or destroying aboriginal antiquities.
7. Social classes in Yucatán.
8. Yucatán's place in the general scheme of Spanish enterprise in America; a. Yucatán in relation to Mexico, Central America and Caribbean; b. problems of defense; c. colonial commerce.
9. Indian uprisings and the general problem of the maintenance of Spanish supremacy.
10. Yucatán during the Mexican wars of independence, and its politico-social evolution in the first generation after independence.
11. The War of the Castes in the mid-nineteenth century.
12. The development of a sentiment of Yucatecan separatism, or quasi-nationalism.
13. The politico-social evolution of Yucatán in recent times, especially since 1910.

The sources to be utilized in the prosecution of this rather ambitious program of research exist in part in the printed histories, documents and reports that have made their appearance from the sixteenth century to the present; and, in part, in extensive manuscript collections in the United States, Mexico, Central America, Spain and other countries. For the present a preliminary survey is being made of the collections, manuscript and printed, in the libraries of the United States. Research in the archives of Spain and Mexico will be started in the year 1932.

RALPH L. ROYS

Books of Chilam Balam and Their Translation

YB 30:157–158, 1931

Yucatán is perhaps the only region in Spanish America where an authentic aboriginal literature flourished throughout the entire colonial period. It is true that during the earlier years of this period we find elsewhere in Mexico and Central America the beginnings of such a literature, but only among the Maya Indians of Yucatán did it continue for centuries to play a real part in the lives of the people. For the ethnologist, the philologist and the historian the importance of such a record can scarcely be overrated.

A large part of this literature consists of the so-called Books of Chilam Balam, which are distinguished from one another by adding the name of the town where the book was written. *Chilam*, or *chilan*, designates a spokesman of the gods, and in this case Balam is probably the family name of the old Maya prophets. This Chilam Balam lived at Maní during the second generation before the Spanish Conquest and foretold the coming of bearded strangers from the east who would establish a new religion. What he doubtless had in mind was the long predicted return of Quetzalcoatl with his Toltec priests, but some rumors of the arrival of the white men in West Indies probably gave to his prophecy a definite character lacking in the prognostications of his predecessors. At any rate the Spaniards arrived in Yucatán at about the appointed time, and thereafter Chilam Balam never ceased to rank as the greatest of the Maya prophets. Inasmuch as prophecies predominated in many of the older manuscripts, it was natural to name these books after the famous soothsayer.

Besides the prophecies, the Books of Chilam Balam also contain brief chronicles, fragmentary historical narratives, creation stories, catechisms for aspirants to chieftainship, and native almanacs. As time went on intrusive European material was added. Sometimes this took the form of the ritual of a hybrid religion in which Christianity was strangely blended with the old native cult, but more often it consisted of translations into Maya of Spanish religious teachings and astrological treatises taken from the European almanacs of the time. We even find the translation of part of one of the Spanish romances and a European agricultural treatise wholly unsuited to the climate and products of Yucatán. Medical prescriptions also occur in some of these books.

There can be little doubt that many of the passages which are purely Maya in character were originally taken from hieroglyphic manuscripts. We know positively that in the years 1685 and 1689 Don Juan Xiu of Oxkutzcab and Diego Chi of Maní transcribed in "letters" certain parts of an old book written in "characters." None of the Books of Chilam Balam which have come down to us today are older than the last part of the seventeenth century, and most of them date from the eighteenth century. Nevertheless the writer is convinced that many passages were copied verbatim from sixteenth and early seventeenth century originals.

During the eighteenth century probably most of the towns of Yucatán had their own Books of Chilam Balam, but the texts of only eight of these are known to us at the present time. We have photographic reproductions of those of Chumayel, Tizimín, Kaua, Ixil, Tekax, and Nah, and copious extracts from the Maní and Oxkutzcab manuscripts. The latter are in the Berendt Linguistic Collection of the Museum of the University of Pennsylvania. Possibly seven more such books are known to us by reputation. The bibliography of this literature is fully treated in Professor Tozzer's *A Maya Grammar* (1921).

The most valuable of the manuscripts mentioned above are those of the Chumayel, Maní and Tizimín. Second only in importance to these the series of chronicles of the Spanish Conquest written by various members of the Pech family and the so-called *Crónica de Calkini*. These last, however, can hardly be classed as Books of Chilam Balam.

The chronicles found in the Chumayel, Maní and Tizimín books been translated and published by D. G. Brinton and Juan Martínez, but the numerous untranslated prophecies found in those same books contain a wealth of historical allusion which may reasonably be expected to go far toward filling the gaps with which the rather meager chronicles abound.

These books are, needless to say, very difficult to read. Many words are misspelled, the syllables are wrongly joined in words and the capitalization and punctuation are rarely of any value. Sometimes the text is illegible along the edges of a damaged page. Also a number of words are neither current in modern Maya nor to be found in the older dictionaries. We have, however, the Berendt copies of some of the books which were made at a time when the manuscripts were in a better condition than at present.

The writer is at present engaged in editing and translating the Chumayel and has adopted the following methods for overcoming these difficulties. Before beginning the actual translation, the text is rewritten with the aid of the Berendt copy and corrected by comparing it with parallel passages or similar phrases

found elsewhere in the related material. This also frequently reveals the significance of a word of doubtful meaning. Deviations from the actual text and the sources of the corrections are recorded in footnotes after the manner of the Oxford editions of the classical texts. Also the text is consistently spelled, punctuated and divided into words, sentences and paragraphs. Finally recognition is given to names of places, personages and gods. All this is only possible by means of the constant use of photographic reproductions of the large body of related material, little of which has ever been published.

Once the above procedure has been followed, some of the apparent difficulties disappear, but the translation still remains difficult enough. This is partly due to the indefinite style of writing followed by some of the Maya writers, and partly because the eighteenth century native compiler was sometimes more than a little uncertain as to the precise meaning of the text he was copying.

As no dictionary of Maya antiquities is available for the reader, the translation must be accompanied by documented footnotes identifying proper names and explaining references to old Maya customs and ceremonies whenever possible. The sources of such explanations are the early Spanish accounts, the works of modern ethnologists, the Maya manuscripts themselves and the archaeological evidence. Maya names of fauna and flora should also be scientifically identified when possible.

Doubts have been expressed in the past as to the possibility of translating these manuscripts. In view of the deficiency of material at the time, such doubts were not unreasonable, but during recent years so much related material has been made accessible to the student that the writer is convinced that the task is now practicable.

ALFRED V. KIDDER

Historical Research

YB 31:123-124, 1932

Mr. France V. Scholes, who is engaged in researches upon Latin American history, with special emphasis upon the history of Yucatán from the time of the Conquest until the present, devoted the period under re-

view to completing an earlier investigation of the relations between church and state during the Spanish régime in New Mexico. He also continued a preliminary check, begun last year, of the printed sources for Yucatecan history, working principally in the library of Harvard University. Mr. Scholes has now gone to Spain for an extended stay, where he will search the archives at Seville and elsewhere for documentary materials upon Yucatán. He will also visit France, England, and Italy. Assisting Mr. Scholes, on a half-time basis by arrangement with Harvard University, is Mr. Robert S. Chamberlain. Mr. Scholes reports that he has found the Archives of the Indies at Seville enormously rich in papers bearing upon all periods. These he is reproducing, by photostat and Leica photography, to bring to the United States for study.

Mr. Ralph L. Roys has undertaken a study of the *Crónica de Oxkutzcab*, also called the *Xiu Chronicle*, which is the book of *probanzas*, or proofs of nobility, of the Xiu family of Oxkutzcab. During the entire colonial period the descendants of certain ruling Maya Indian families in Yucatán were considered to be *hidalgos* and "native lords" and enjoyed many privileges. They were exempt from tribute, and the local community was compelled to cultivate their lands, garner their crops, rebuild their homes when necessary, and supply them with domestic service. Such a procedure kept the most influential native families loyal to the Spanish government, and the policy was a notably successful one.

Believed to have been of Mexican origin, the Xius were noted for their political shrewdness prior to the Spanish conquest, and in their papers we find much evidence of the same judicious opportunism in their relations with the Spanish authorities and missionaries.

The documents consist of Maya petitions from the heads of the family confirmed by the Defender of the Natives, Spanish decrees by the Governors, often accompanied by Maya translations, and a confirmation of the latter in Maya signed by the local officials. There is a Xiu family tree beginning five or six generations before the Spanish conquest, and the map and Maya minutes of the famous Maní land convention of 1557, which contain much ethnographical material hitherto unpublished. On the back of an interesting personal letter is a Maya chronicle of the time of the Conquest, stated by its writer to have been transcribed from a hieroglyphic codex. This contains data which make it the basis of one of the important correlations of Maya and Christian chronology. We also find a wealth of detailed information as to the manner in which Maya local institutions were adapted to the needs of the Spanish colonial administration.

The collection has great linguistic value, as it presents a series of dated Maya texts covering the greater

part of the colonial period. Here we may trace the changes which occurred in the language at a time when a certain amount of European culture was being introduced into Yucatán and combined with or superimposed upon the native customs and beliefs. The series should also constitute a standard by which we may approximately determine the age of other Maya texts which bear no date.

Mr. Roys has completed the transcription of all the documents of this collection, many of which are faded, torn, or badly written, and the material has been translated and annotated down to the year 1738. The series ends in 1817. The publication of the *Crónica* will contain, by way of introduction, a history of the Xiu family compiled from other sources and something of Spanish ideas regarding the status of "native lords" in New Spain. An appendix will present other versions and one other map of the Maní land convention; another will discuss the meaning and possible origin of the Maya family names occurring in these papers.

RALPH ROYS

Family Histories in Yucatán

YB 32:104–106, 1933

In addition to reading the proof of the *Book of Chilam Balam of Chumayel* [Chapter 9.2], have made a preliminary survey of a large number of Maya texts from the Spanish archives at Seville which have been discovered and photographed by Mr. F. V. Scholes. These consist chiefly of letters from Maya chiefs to the King of Spain and complaints by the natives of Yucatán of abuses committed by certain Spanish Governors. These promise to be of the greatest value to the study of the linguistics and the history of Yucatán,

Much of the year has been spent in work connected with the collection of Xiu family documents now in the Peabody Museum and known as the *Crónica de Oxlutzcab*. The general character of these papers has already been outlined in a previous report [Chapter 9.3]. This work has involved a comparison of the material with the published and manuscript sources for the history of Yucatán. Unpublished documents have been found in the libraries of Tulane University and the University of Pennsylvania which parallel and

amplify the ethnographical data occurring in the Xiu collection; these have also been edited and translated and will form a part of the Xiu publication.

The Xiu papers come to an end with the fall of the Spanish regime in Yucatán. They present an unbroken history of this famous family from about the year 1400 A.D. until 1817. This is a unique record, as no other aboriginal American family, not even those of the Montezumas or the Incas, can be traced in this manner. Accordingly, a field trip to Yucatán was made for the purpose of continuing the history of the Xiu down to the present time. The complete record of this family is of especial interest, for they flourished as rulers for at least five and one-half centuries, were privileged nobles for the next 2080 years, and now for more than a century they have earned their bread by the sweat of their brow.

Other objects of this trip were a study of the extent of the former native states as outlined in the sixteenth century Maya land treaties and an examination of the parallels existing between the Books of Chilam Balam and the archaeological remains in Yucatán.

In Yucatán a personal search of the Church and municipal archives, supplemented by interviews with many members of the Xiu family, resulted in the acquisition of a large body of genealogical material. This is very complete for the descendants of the last noble head of the family, of whom 111 persons, living or dead, were found in the sixth generation alone. Also practically all the living Xiu who could be located were traced back to ancestors listed in the 1817 patent of nobility, the last of the collection. The pedigrees obtained offer much that is of interest to students of genetics. The ages of mothers at the time of the birth of their oldest children should have a bearing on the theories of embryologists regarding puberty, adolescence and maturity. The material collected also furnishes information regarding size of families, child spacing, percentage of illegitimate births, infant mortality and comparative ages at death. Causes of death were noted wherever possible. The direct descendants of the last noble head of the family have not done particularly well during their century of economic struggle, for they are less prosperous and show a higher family groups which were the rate of infant mortality than the collateral subjects of this study. The ethnographical material is of especial value and its study was greatly aided by the field trip. Journeys were made along the borders of the ancient native kingdoms as indicated by the documents, and it was discovered that a strong feeling of sectionalism still exists and follows the lines of the old frontiers. Not only was this feeling reflected in the Maya land documents of the colonial period, but it has persisted down to the present time. A considerable portion of the country traversed was practically

depopulated for many years during the War of the Castes, the inhabitants having retired to more protected centers of population. Inquiries at the towns and hamlets on both sides of the line elicited the information that the present inhabitants had returned from their own side of the old frontier stopping short at it and rarely penetrating the territory of what had been the neighboring state in pre-Columbian times. The Spaniards found Yucatán divided into a number of independent states, which were believed to have dated only from the fall of Mayapán in the middle of the fifteenth century A.D., but conditions suggest that a sectionalism, which has persisted in spite of almost 400 years of political unity under foreign rule, must have required a much longer time for its development than the comparatively, short period which elapsed from the destruction of Mayapán until the Spanish Conquest.

A search was made for the site of the ancient town of *Cetelac*, which is said by the Book of Chilam Balam of Chumayel to have been a depot for the collection of tribute at the time of the conquest of Chichén Itzá by Mayapán about the end of the twelfth century A.D. A place of this name was located only a kilometer from the ruins of Yaxuná, the western terminus of the famous causeway and closer to the ruined city than the town from which the latter takes its name.

A visit to Mayapán, the former capital of northern Yucatán was of great interest. Mexican architectural features, such as triple doorways and serpent columns, correspond to the Maya tradition which associated the Nahuatl term, *tecpan* (government house), with this city. Although the mere use of columns does not necessarily imply a *tecpan*, the large number of columned structures at this site are of such a character as to indicate their resemblance to the council halls described by the Spanish conquerors on the highlands of Mexico. They are too numerous to have belonged only to the Mexican mercenaries stationed at Mayapán but correspond rather to the presence of the headchiefs of northern Yucatán, all of whom were said to have been obliged to reside at the capital and govern their own districts from a distance.

It is at Chichén Itzá, however, that we find the greatest number of analogies between the Books of Chilam Balam and the remains; and these strangely enough, are largely confined to the Mexican period of this city. It shows the strong influence exerted by this foreign culture upon the native population, when we find these alien traditions still preserved in the Maya literature of the Spanish Colonial period, in spite of the hatred with which the Mexicans were regarded in Yucatán.

Some of the statues at Chichén Itzá amply justify the Maya reproaches that the Itzá were immodest and indecent. Here, too, are sculptures of the animals which

symbolized the Toltec warrior orders, the four trees and birds of the creation story, the rattlesnake and the "house of skulls" (the *tzompantli*), all of which figure in the Books of Chilam Balam.

The examination of the local archives, as well as interviews with a large number of the native population, afforded an opportunity to make a study of Maya family names and their distribution. Some are confined to certain localities, while others are widely spread over the entire country. The meanings of some of these names, which are those of mammals, birds, insects, trees and plants, suggest a former clan organization among the Maya. A few are Mexican, while others, difficult to translate, seem to correspond to the names of certain tribes or nations. The value of these names to the study of ethnology is apparent, and this material will be presented in an appendix to the Xiu Chronicle.

9.5.

FRANCE V. SCHOLES

History of Yucatán Project

YB 32:114–119, 1933

The general program of research for the History of Yucatán Project was discussed in the *Year Book* for 1931 [Chapter 9.3]. The first group of studies which has been started as part of that general program will deal with the Spanish Conquest and with the development of a Hispano-Indian society during the succeeding century and a half. The sources on which these studies will be based consist of printed chronicles and documents and of unpublished papers preserved in public and private archives and libraries in Europe and America. Most of the year 1931–32 was given over to a survey of the available printed materials in preparation for a comprehensive program of research in European archives and libraries. Archive work was started in April 1932, and the past 15 months have been devoted to an intensive search for manuscript materials for the history of the general Yucatecan area in the major collections of Spain.

As the result of a cooperative arrangement by Harvard University and the Carnegie Institution, I have had the active assistance, since June 1932, of Mr. Robert Chamberlain, graduate student in Harvard, who is making a study of the career of Francisco de Montejo,

Adelantado of Yucatán, for his doctoral dissertation. Mr. Lewis Hanke, also a graduate student in Harvard and Amherst Memorial Fellow for the year 1932–33, who is writing a dissertation on theoretical phases of Spanish Indian administration, rendered valuable assistance on numerous occasions. Acknowledgment should also be made of the courtesy of Professor C. U. Clark, formerly on the staff of the Smithsonian Institution, who gave me access to his notes on Central Americana in European collections, accumulated during two years of research for the Smithsonian.

The most important Spanish depository of manuscripts relating to America is the Archivo General de Indias in Seville. For the history of Yucatán during the period of Spanish domination it is especially rich, and a conservative estimate of the total bulk of papers directly relating to Yucatán would not be less than half a million pages. Besides searching the files of the strictly Yucatán papers, it has been necessary also to run through the vast series that pertains to general colonial policy and to the history of New Spain proper and of Guatemala. The sheer bulk of the materials made necessary the use of rapid methods of reproduction of the more important documents for future use and reference at home. Photostats were made of certain items, but the major portion of the reproductions were made with the Leica camera and 35 mm moving-picture film. Enlarged prints have been made of a part of the films, but the amount of enlarging has been limited by budgetary considerations. Part of the unenlarged films can be read from projection, but this method has distinct limitations, of which not the least important is eyestrain. To the officials of the archive and especially to the director, Sr. D. Juan Tamayo, the Institution is deeply indebted for their kind consideration and sympathetic cooperation in making possible such rapid reproduction of materials essential to the success of the project.

The nature and contents of the materials which have been reproduced up to the present time are briefly indicated as follows: 1. Letters and reports of the provincial governors of Yucatán for the period to 1660; 2. Letters of the treasury officers of the province to 1660; 3. Correspondence of the cabildos of Mérida, Valladolid, and Campeche to 1700; 4. Letters and papers of the bishops of Yucatán and the cathedral chapter, of Mérida to 1700; 5. Selected letters and petitions of private individuals, secular and ecclesiastical, taken from the general series of private correspondence for the viceroyalty of New Spain and the presidency of Guatemala; 6. Selected correspondence of the Audiencia of Guatemala, the governors and bishops of Honduras, and the treasury officers of the Guatemala district for the period prior to 1550; 7. Registers of royal orders for the province of Yucatán for the sixteenth century; 8.

Treasury accounts for the province of Yucatán for the sixteenth century and the first two decades of the seventeenth; 9. A book of tribute assessments for Crown and encomienda towns in Guatemala, Honduras and Yucatán made at the end of the 1540s; 10. Selected parts of a series of more than a 100 legajos of papers relating to confirmations of encomiendas in Yucatán, sixteenth to eighteenth centuries; 11. The residencias of Montejo, Loaisa, Quijada and Céspedes, governors and alcaldes mayores of Yucatán in the sixteenth century; 12. Linguistic materials from the residencias of seventeenth century governors; 13. Trial records of private and state lawsuits illustrating phases of the career of Montejo, and the practice of encomienda administration in Yucatán; 14. The file of papers relating to Landa's *auto de fe* against Indian idolatry in 1562 and Bishop Toral's investigation of the same; 15. A matrícula, or village by village census, of encomienda Indians in Yucatán for the early 1680s; 16. Four sets of documents on the theory of Indian administration, especially the problems of personal-service, perpetuity of encomiendas, and levy of tithes, reproduced in cooperation with Mr. Hanke; 17. Part of a long series of documents dealing with the Petén expeditions of the 1690s.; 18. Memorials, reports and lawsuits relating to a serious controversy between the Protector of the Indians and leaders of the Spanish ruling minority in the decade of the 1570s.

Work in the Archivo General de Indias has been carried forward without interruption during the past 15 months. Meantime, investigations have been made in other Spanish collections. In the Archivo Histórico Nacional, Madrid, search was made in four sets of documents. In the papers proceeding from the Mexico tribunal of the Inquisition a few references to inquisitorial trials relating to Yucatán were found and will serve as a guide to future investigation in the papers of the Inquisition in the national archive of Mexico. A cursory examination was made of the residencias of late eighteenth century governors of Yucatán in the Council of Indies section. Groups of Franciscan papers were examined in the hope of finding information concerning Fray Diego de Landa during his residence in Spain in the 1560s, but the results were entirely negative. In the unpublished parts of the *Cartas de Indias* series several valuable items were found, of which the most interesting are a letter of Fray Luis de Villalpando denouncing the conduct of Yucatecan encomenderos and a brief survey of mission organization in Yucatán in the second half of the sixteenth century. Mr. Chamberlain also made a careful examination of the unpublished parts of Ayala's famous dictionary of government and legislation for the Indies and of parts of the *Cedulario Indico* of which it is the index.

The manuscript division of the National Library, Madrid, possesses a rich collection of Americana, but it contains little of special interest for Yucatán. In the library of the Academy of History, the most famous item for Yucatán is Landa's *Relación de las Cosas de Yucatán*, many times published. Nothing more of vital importance for Yucatán was found. Mention should be made, however, of the copy, partly abridged, of Lic. Tomás López. López was a judge of the Audiencia of Guatemala and special visitor of the province of Yucatán in the early 1550s. His labor in Yucatán had to do mostly with Indian affairs and his name is always associated with a famous set of ordinances for the regulation of the same treatise on the climate, geography, flora and fauna, and aboriginal customs of the Indians of Middle America. This treatise has no great value as a whole, but the chapter on heathen gods and ceremonial practice, especially the short section on sacrifices at the cenote of Chichén Itzá, has some interest for the Americanist. The author of this report plans to publish this chapter. Due to the kind intervention of Professor Antonio Ballesteros and the Duke of Alba, Mr. Chamberlain was permitted to spend several days in the private archive of the Duke of Fernán Núñez examining a series of papers relating to the Montejo family and later holders of the title of adelantado of Yucatán. He found important materials concerning the ultimate disposition of the lawsuit between the Montejo family and the Crown resulting from the removal of Montejo as governor of Yucatán in 1549, and also detailed reports of the tributes of certain Indian villages in Yucatán later enjoyed by the Duke of Montallano, in whose family the title of Adelantado is still held. The Palace Library, formerly the private library of the kings of Spain, has been opened to students, and preliminary investigations have been made by Mr. Chamberlain and myself, but no report can be submitted at present concerning possible Yucatán manuscripts which it may contain. Finally, inquiry has also been made at the Convento Grande de San Francisco, the Naval Museum, the Ministry of Hacienda, and the Delegación de Hacienda, in all cases with negative results.

Brief visits have been made to a few collections outside Madrid: the Escorial; the provincial library, cathedral library, and Delegación de Hacienda in Toledo; and the Archivo de Simancas. The provincial library in Toledo possesses an interesting original manuscript on Vera Paz and the Petén written in 1635 by the alcalde mayor of Vera Paz. Permission to reproduce this manuscript has been sought. In Simancas the Yucatán materials are few and scattered for the sixteenth and seventeenth centuries. The most important are in the diplomatic series and relate to the intrusion of foreign corsairs and traders in Yucatecan waters.

The archive researcher is always inspired by something of the spirit of the professional prospector. He lives in the hope of finding some unexpectedly rich collection of letters, or of rediscovering some long lost chronicle. For the student of Yucatecan history there are many "finds" still to be made, for the list of missing manuscripts, linguistic and historical, is long. Realizing that the major Spanish collections had been combed many times for these lost manuscripts, I hoped that in ecclesiastical archives, especially the archive of the Franciscan Commissary General of the Indies, if still intact, some of them might be brought to light. To this end I sought the aid of my colleague, Dr. Stork, in order to obtain introductions to Spanish churchmen who might assist me in obtaining access to important collections. At his request His Excellency the Nuncio in Dublin sent me letters of introduction, one of them to the Nuncio in Madrid, who, in turn, put me in contact with several learned Spanish Franciscans. Unfortunately, the result of all this courteous cooperation has been only to indicate beyond any doubt that the once great Franciscan archives, especially the papers of the Commissary General formerly kept in the Convento Grande de San Francisco, Madrid, have been hopelessly dispersed, or in considerable part lost or destroyed. The same is true of the archives of those Franciscan houses which sent forth such men as Landa and Villalpando to labor in the missions of Yucatán. Fragments of these archives are now deposited in the Archivo Histórico Nacional, Madrid, but the legajos that were examined contain nothing of value for the Yucatán project. Thus was dashed to the ground my greatest hope of finding any of the important missing linguistic and historical writings of those Franciscan scholars who illumined the intellectual life of Yucatán in the colonial period.

In the Archivo General de Indias a few minor "finds" have been made. The most important is the relación of the customs of the Indians of Yucatán written in 1582 by Gaspar Antonio Chi, often regarded as the chief authority on whom Landa relied when writing his *Relación de las Cosas de Yucatán*. The nature of Gaspar Antonio's 1582 treatise has long been known through Cogolludo's use of it, but it was hoped that the original, if ever found, would contain much new information not used by that indefatigable ecclesiastical historian. The signed manuscript of Gaspar Antonio's treatise has been found in a series of miscellaneous papers in the Archivo General de Indias. Unfortunately it consists of only two folios, of which half of each has been torn away. Comparison with Cogolludo will make possible the reconstruction of almost every mutilated line in the original; in fact, Cogolludo used the original so well that its rediscovery will add little to our present stock of knowledge.

The general objective for which this archive program is merely the preparatory stage is a rounded study of Hispano-Indian society in Yucatán during the sixteenth and seventeenth centuries. It was during that period that colonial society took form and the fundamental patterns of the culture of Hispanic America were permanently fixed. The eighteenth and nineteenth centuries witnessed the culmination of certain trends and the reorientation of others, but the basic elements of society and culture were determined in that early period of readjustment during the first century and a half subsequent to the Conquest. Such a general view of Hispano-Indian society in Yucatán prior to 1700 must, however, presuppose the execution of certain preliminary and specialized studies in the form of articles or monographs in which the available materials can be dealt with in adequate detail.

1. A thorough study of the career of Montejo is needed in order not only to do justice to one of the great figures in the conquest of Spanish North America, but also to set the Yucatán phases of it in proper relation to the whole. Mr. Chamberlain's work on Montejo will fill this need. It will be based on all the available manuscript and printed sources, and will deal with Montejo's labors as an associate of Cortés, the preliminary expeditions to Yucatán and Tabasco, his term as governor of Honduras and Chiapas, the final conquest of Yucatán, and the organization of provincial administration and society to 1549.
2. Another figure in the early history of Yucatán whose career requires critical revaluation is Bishop Diego de Landa. Landa is known to us mostly for two things: his treatise on the Indians of Yucatán and the early history of the Spanish province and the famous *auto de fe* against Indian idolatry in 1562. The story of the Maní incident has never been properly presented, although J. T. Medina (1905) dealt with certain phases of it in his book on the beginnings of the Inquisition in America. Fortunately the Archivo General de Indias possesses the complete record of this affair, as well as numerous supplementary letters and reports, so that a critical study of this celebrated case is possible. Equally important is a survey of Landa's episcopate and of those conflicts of interest in which he took a leading part. A critical estimate of Landa's career may thus be made the basis of a detailed survey of the fluctuating conditions of provincial development during the first generation subsequent to the Conquest.
3. A brief monograph on the population of Yucatán in the sixteenth and seventeenth centuries will be valuable both for the historian and the ethnologist. An adequate estimate can be made by using the tribute payments as a basis, comparing the results thus gained with two or three special estimates that were made during the first century following the Conquest and with the matrícula of encomienda Indians for the early 1680s.
4. Adequate materials are now available for the investigation of numerous phases of Indian administration, of which the most important is the problem of the encomienda. The encomienda was introduced in Yucatán with the Conquest, and it lasted as a vital element of provincial life until the last quarter of the eighteenth century. Moreover, the proportion of encomienda villages to those administered by the Crown was approximately 12 to 1, at least during the sixteenth and seventeenth centuries, so that it is difficult to overestimate the overshadowing importance of this institution in provincial society. In its ramifications, it was related to every other element of Yucatán life; in fact, analysis of this institution and its workings may be regarded as the warp on which the story of provincial society must be woven. The Archivo General de Indias contains more than a 100 legajos of documents relating to the encomienda in Yucatán, of which selected parts have been reproduced.
5. Treatment of the subjugated Indians is but one phase of the general Indian problem. The unconquered and fugitive Indians of the interior of the peninsula of Yucatán were always a matter of serious concern to both State and Church. Series of manuscript materials now brought to light make necessary a re-examination of this entire question, not only in relation to some of its earlier phases, but also for the classic Petén expeditions of the late 1690s as related by Villagutierre. The original materials from which Villagutierre wrote his history of the conquest of the Itzá are preserved in the Archivo de Indias, and reproduction of these papers for the use of the project has already been started.
6. For ecclesiastical affairs, there are several topics which call for special treatment. I mention only three: a. The beginnings of ecclesiastical organization and government; b. Statistical studies of missionary enterprise; c. The role of the mission friar as defender and exploiter of the Indian.
7. Although the materials which have been reproduced are essentially historical, they contain valuable information, direct and incidental, for the ethnology, ethnography and linguistics of Yucatán, Tabasco and the Petén. The survival of Indian ritual and ceremonial practice is discussed in several groups of papers. It is hoped that some contribution may be made to the knowledge of the shifting Indian groups in the interior of the peninsula, especially in the area between Campeche and Tabasco. Mr. Roys has found the cacique names that appear in numerous letters and legal documents valuable for his own studies. A document concerning the services of Gaspar Antonio Chi contains a few details concerning the Xiu family. Rather full information concerning Indian family names is found in the matrícula of encomienda Indians noted above. Numerous incidental statements will help to illustrate the character of Indian village organization and the agricultural bases of Indian economy. But the most important materials are linguistic. Approximately

three thousand pages of new Maya text, Spanish translation and accompanying explanatory documents will be available as soon as the program of reproduction is complete. A few of the new Maya texts date from the sixteenth century, but the major portion are found in the residencies of seventeenth and eighteenth century governors, and consist of Maya translations of official decrees, depositions of Indian witnesses and related items. Much of this materials of a routine sort and there is considerable duplication of phraseology. On the other hand, a considerable number of the texts seem to have been written by native scribes, and Mr. Roys has informed me that some of the texts are unique in that they may serve as examples of the language for areas for which no known specimens have been available heretofore.

The archive program will be continued throughout the year 1933–34, with investigations in Spain, France, Italy and England.

9.6.

SYLVANUS G. MORLEY

History of the Xiu Family

YB 33:105, 1934

An activity which has engaged the attention of Dr. Morley in such time during the past three years as he has been able to spare from administrative duties and preparation of his monograph upon the hieroglyphic inscriptions of Petén has been study of the history of the Tutul Xiu, the former ruling family of Uxmal, one of the largest pre-Columbian sites in the Maya area.

The head of the family at the time of the Spanish Conquest, Ah Kukum Tutul Xiu, lent effective aid to Francisco de Montejo, the conqueror of Yucatán, and, later, Ah Kukum's Tutul Xiu grand-nephew was ennobled because of the services of his great-uncle to the Crown. Ah Kukum Xiu, later baptized as Francisco de Montejo Xiu, made a genealogical tree of his family, going back four generations before himself, which was later carried forward another, four generations by his great-great-grandnephew. This tree, compiled about 1560, gives the main line of descent for nine generations from about 1418 to about 1622. The family papers accompanying this tree cover slightly more than two centuries, 1608 to 1817. They consist chiefly of petitions of

successive heads of the Xiu family to colonial officials throughout the Spanish Colonial Period requesting confirmation of their titles of nobility and the corresponding tax exemptions, rights of personal service, etc. These papers begin with the petition of the grand-nephew of Ah Kuku, one Pedro Xiu, and come down to the petition of Antonio Xiu II in 1817; they present a total of eight generations and 11 heads of the family. There is a satisfactory overlap of three generations between the tree and the family papers, the last three heads of the family on the tree being the same as the first three as given in the papers.

Finally, from living informants, chiefly a Felipa Xiu, who died during the present year at the age of 67, the family history was secured back as far as her great-grandfather, Andrés Xiu, born in 1789. Both her great-grandfather, Andrés, and her grandfather, Buenaventura, appear in the last family paper, the petition of Antonio Xiu II, dated in 1817, so that there is an overlap of two generations between the family papers and the data derived from living informants. These three sources, the family tree (1418–1622), family papers (1608–1817) and the information received from living Xius (1789–1934), cover slightly more than five centuries of the family history, a total of 20 generations in the main line of descent. No other aboriginal New World family, with the possible exception of the Incas of Peru, can boast so long a recorded genealogy.

In collaboration with Ralph L. Roys of the Division staff, Dr. Morley is preparing a history of the Xiu family, which it is hoped will be published in 1935.

9.7.

RALPH ROYS

Researches in Maya Life in the Sixteenth Century

YB 33:105–108, 1934

Genealogical data previously collected in Yucatán for the history of the Xiu family [Chapter 9.3] have been prepared by Mr. Roys for publication. He has tabulated, annotated and charted these pedigrees in a form suitable study and comparison. Dr. Morley, who is collaborating in this work, completed a historical account of the family down to the Spanish Conquest and has compiled a large master-chart of the genealogy of the family the early fifteenth century to the present time.

Besides the documents already transcribed and translated for publication, an extensive study has been made in collaboration with Dr. Morley of historical sources connected with the history of the Xiu. This comprises the published histories and relaciones as well as many Maya and Spanish manuscripts. As the Xiu were one of the most prominent native families in Yucatán, both before and after the Conquest, the historical ramifications of their annals are wide-spread. One especially interesting example of such historical sources is the collection of probanzas, or proofs of nobility, Gaspar Antonio Chi, whose mother was a Xiu and whose father and uncles played an important part in the events leading to the Spanish Conquest. We are indebted to Mr. Scholes for the opportune discovery and reproduction of the probanzas [Chapter 9.3] as well as for the census lists and many other Maya texts and Spanish documents cited in this report.

Both the examination of the Xiu records and the study of the Books of Chilam Balam have brought out the need for a closer investigation of Maya proper names. The list of Maya family names which still survive in Yucatán [Chapter 9.3] has been greatly amplified from signatures to Maya document and census rolls of the colonial period. Such records are more dependable for linguistic purposes than most of the Spanish documents, as they were written by native scribes. Even the notations to the census rolls were frequently written in Maya. From these and other sources, it has been possible to compile a list of 250 Maya family names. A considerable proportion of them has been translated and classified according to their meanings, and they have been compared with Maya place-names, an amazingly large number of which still survive in Yucatán. A classification has also been made of the latter.

The Maya family name, which was perpetuated in the male line, survived the Conquest, but the old pagan pre-names were abolished and replaced by Spanish Christian names when the Indians were baptized. Two varieties of pre-names are well known: one indicating a man's profession or office, and the other, derived from his mother and preceded by the prefix *na*. The Maya called the latter the *naal*, and there were also two other classes of pre-names, which they called the "boy-name" and the "jesting-name." Many of the "boy-names" are referable to fauna-names, especially those of birds, while some of the "jesting-names" appear to be descriptive. It seems to have been possible for a single person to have borne all four names. The *naal* names of 146 persons have been tabulated and classified according to the localities where they lived. "Boy-names" of 50 individuals were collected, but it was impossible to identify more than six "jesting names."

The preservation and the legal recognition of the native Maya nobility during the entire Spanish colo-

nial period have hitherto received little attention. Some time was spent at the Huntington Library, where a study was made of the legal standing and history of Maya nobility. The sources for study had been suggested by Mr. Scholes and were the collections of statutes enacted for the Indies and the works of Solórzano, the famous commentator on Spanish Colonial law; and the information gathered forms an introduction to the legal papers of the Xiu collection.

Beginning with the Laws of Burgos enacted in 1512, we are able to trace in the subsequent legislation for the Indians the development of a policy which finally became an accepted institution and was admitted without question by the later colonial administrators. In Yucatán, as elsewhere, it was found convenient at first to allow the former native rulers and their descendants to continue to govern their people under Spanish supervision. Later they were deprived of their hereditary political power, but the old nobility continued to form a privileged class, exempt from taxation and personal services and sometimes still supported by the community in which it lived. Although such a policy increased the burden laid on the taxpayers, it kept the most influential Indian families on the side of the Spanish regime.

In addition to their linguistic and historical value, the records from the Archivo General de Indias continue to furnish ethnological material of considerable interest. Little has been known of the extended households composed of a number of families, which were observed by the first missionaries. This manner of living was soon abolished, and only one family was permitted to live in each house. A 1570 census of two towns on the island of Cozumel, however, reveals the survival of this important social feature, due no doubt to the fact that missionaries rarely came to this island. Here many of the notations are in Maya, but with it we find the Spanish report of a Franciscan friar describing conditions.

Husbands and wives are listed according to the house in which they lived, each house containing from one to seven families. Some of them have the same family names as that of the owner of the house; while these may have been brothers and sisters of the head, it seems more likely that they were sons and daughters, since Landa states that the newly married lived close to the homes of their fathers or fathers-in-law. There were also other inmates of these houses whose connection with the head of the household is difficult to explain.

Another apparent survival of these large households is indicated in the 1571 census of Tixchel, a Chontal town in southwestern Yucatán and close to the border of the Maya speaking area. Here we find many groups of persons, usually sons-in-law and

brothers-in-law of the head of the group, whose relationship is actually stated. Only rarely are sons, brothers or nephews mentioned. The names themselves are of especial interest. Some are the same as those found among their Maya neighbors; nevertheless their system of nomenclature seems to be different from the Maya. It is noteworthy in this connection that a Chontal relación by the governor of Tixchel reports that his ancestors originally came from Cozumel.

Just as the non-Spanish documents from the region of Lake Amatitlán are found to be written in both Pokomam and Nahuatl, so the reports from the Chontal speaking area are written in both Chontal and Nahuatl. This confirms the observations of sixteenth century missionaries, who noted that many Central American Indians were bilingual and communicated with the Spaniards and other foreigners in Nahuatl. From the Yucatecan Maya area, however, we have only Maya and Spanish reports. Here Maya was the only native language spoken, and Nahuatl ceased to be the *lingua franca* of the country.

9.8.

FRANCE V. SCHOLES

History of the Yucatán Project

YB 33:115–117, 1934

During the past year the general program of archive research in Spain, as described in the last annual report, has been carried forward without interruption, and by September 1 most of the work will have been finished. Most work during 1933–34 has been carried on in the Archivo General de Indias in Seville. Series of papers in which investigation had been started during the preceding year were completed, and progress was made in sorting some of the long series of Indiferente General in which the findings were numerous but sometimes important. Sr. Santiago Montero, an investigator of long experience in Seville, was employed for several months in this dreary task of sorting and searching. Reproduction of materials by Leica camera and by photostat was continued during the entire year, and a considerable quantity of enlarged prints was made from selected parts of the Leica films. The most important groups of papers reproduced during the past year were: a. Correspondence of provin-

cial governors of Yucatán for the period 1660 to 1700; b. Correspondence of treasury officers of Yucatán for the period 1660 to 1700; c. Additional portions of the Yucatán encomienda series d. Additional legajos on the conquest of the Petén; e. A considerable quantity of materials on Spanish policy relating to the aboriginal population of America, especially questions of encomienda, tribute and personal service, from the Patronato and Justicia sections and from the Santo Domingo, Mexico and Guatemala parts of the Audiencia series; f. The remainder of the Maya texts and accompanying Spanish documents from the residencia series; g. Selected parts of the general registers of cédulas and from the special registers for Mexico and Guatemala; h. Probanzas of services of conquerors of Yucatán. Perhaps the most interesting find was a Chontal text of seven pages describing the history of certain towns and chieftains of the Tixchel area.

In collaboration with Mr. Hanke several items relating to general Indian policy were photographed in the National Library and the Palace Library, Madrid, the Cathedral and Public libraries in Toledo, the library of the Escorial, and the National Library, Paris.

Mr. Chamberlain spent several weeks in Simancas, Valladolid, Burgos and Salamanca searching for materials on the Montejo family. In the summer of 1933 he also had the opportunity to examine portions of the archive of the Duque de Fernán Núñez which contain important Montejo records, but when he wished to re-examine some of the papers in June 1934, he was informed that the archive was closed and that the Montejo papers would be published some time in future by the Duque de Fernán Núñez himself.

In October 1933, Mr. Scholes spent a day in Cifuentes, the ancestral home of Bishop Landa, but no papers of any importance were found.

As a result of the past two years of intensive archive and library work, there has been accumulated a vast body of source material for the history of Yucatán during the century and a half succeeding the Spanish Conquest and for related general problems of colonial administration. The immediate task ahead is to study and digest these materials. Mr. Chamberlain has made rapid progress on his study of Montejo, and he expected to have completed his reading in the manuscript sources before leaving Spain in August. The problems on which Mr. Scholes expects to begin intensive work during the coming year deal with the history of Yucatán in the second half of the sixteenth century, especially problems of population, the introduction of Spanish institutions and the Catholic faith, and the career of Bishop Landa.

It must be stated that many important sources, noted in older writings on Yucatán or in the well-known bibliographical lists, are still missing. But it is

increasingly clear that these missing items are not likely to be found in great collections. There remains, of course, the possibility that in some of the hundreds of lesser archives and libraries, state and private, lay and ecclesiastical, some of these long lost manuscripts may some day be found. But the task of journeying from town to town in search of lesser collections was so great and the chance of success so remote that it was neither expedient nor feasible to test out more than a few places where definite leads had indicated the possibility of success. Late in June a rumor was received that some of the Avendaño manuscripts had once been in the archive of the Depósito Hidrográfico; which is now part of the Museo Naval, Madrid, but inquiry at the Museo Naval brought the reply that the collection contains no Avendaño papers at the present time. It is known that important groups of Americana are still in private hands, but discreet inquiries, official and private, made it clear that access to such collections will not be given at present. The problem of the archive of the Franciscan Commissary General of the Indies is still an unsolved riddle, but it is sincerely hoped that this important collection will some day be discovered and put at the disposal of scholars.

In conclusion, it is only fitting to express the sincere thanks of the Carnegie Institution to the librarians and archivists of the collections in which work been carried on during the past two years, and in particular to Sr. D. Juan Tamayo, chief of the Archivo General de Indias. The courtesy and loyal cooperation of these scholars contributed much to the successful completion of the general archive and library program.

9.9.

FRANCE V. SCHOLES

History of the Yucatán Project

YB 34:146–148, 1935

During the year 1934–35 considerable progress has been made on the following special studies on the history of Yucatán since the Spanish Conquest: 1. The life of Francisco de Montejo, Adelantado of Yucatán; 2. Estimates of the population of Yucatán during the colonial period; 3. The beginnings of the encomienda; 4. The history of the cacicazgo of Acalán-Tixchel, 1526–1612; 5. Landa and the *auto de fé* of 1562; and 6. Problems of Indian labor, especially during the decade of the 1570s.

Francisco de Montejo deserves to rank with the half-dozen greatest captains in the conquest of Spanish North America. His sphere of action was not limited to Yucatán and Mexico. During the years 1536–39 he served as governor of Honduras, and he was recalled to activity in that area in the 1540s after the death of Alvarado. It was his ambition to govern a vast area stretching from Copilco to the Río de Ulúa, and by a cédula of 1533 he was actually given authority over this entire region which comprises a large part of the Maya area. The forces of nature, reverses of various kinds, the rivalry of Alvarado, and the ultimate restriction of his authority by the Crown made it impossible, however, for him to assert control over this huge principality. Montejo was an enlightened administrator of the Cortés type, and his government of Honduras, especially his policy regarding the Indians, is a bright spot in an otherwise sordid story. Mr. Chamberlain hopes to have his biography completed in 1936.

The remaining five studies listed above are being prepared by Mr. Scholes. The nature of the manuscript sources makes it possible, in fact necessary for the sake of efficient use of the documents, to carry on the several investigations at the same time. Estimates of population, especially during the sixteenth and seventeenth centuries, must be based in part on the levy of tribute, and inasmuch as more than 90 percent of the villages of Yucatán were held in encomienda, the close relationship between the problems of population and encomienda is obvious. We have tribute rolls and, in some cases, rough census reports at conveniently placed intervals, 1549, 1606, 1689, 1789. Supplementary partial reports are available for some of the intervening periods. Students of archaeology often postulate a dense population for Yucatán in ancient times. During the period since the Spanish Conquest, however, the population has never been large. In 1549 the number of tribute payers was probably between 57,000 and 60,000. Estimates of 50,000 tribute payers are found for later years of the sixteenth century. In 1789 the population of Yucatán and Tabasco was reported to be 364,621, classified as follows: Spanish and mestizos, 54,465; Indians, 264,955; negros and mulattos, 45,201. The population of Tabasco was 30,640.

The history of the encomienda requires a preliminary statistical study of the individual holdings and a detailed list of villages, the amount of tribute paid by each, and the encomenderos to whom the payments were made is being prepared. This list used in connection with the documents on the sale and transfer of land in the notary records in Mérida will provide working basis for the formulation of valid conclusions on the moot question of the relation of the encomienda to the development of the hacienda system Yucatán.

The monograph on the cacicazgo of Acalán-Tixchel will clear up certain phases of the history of the region south, east and northeast of the Laguna de Términos. At the time of the conquest the cacicazgo of Acalán (the town of Acalán being the same as Izancanac) was an area close to the Laguna de Términos. After the conquest some of the Indians were moved Tixchel between the laguna and Champotón, and the government of this pueblo was taken over by Pablo Paxbolon, descendant of the caciques of Acalán. The later history of the Tixchel area deals mostly with the services of Paxbolon and of Francisco and Martin Maldonado, his son-in-law, and grandson, in the conversion and reduction of Indians in the interior of southern Yucatán. The story as told in a series of detailed reports raises one interesting problem. A probanza of the services of Paxbolon and his ancestors is given in an Indian language, said to be Chontal. This confirms the statement in the Ponce relación that the Indians of Tixchel spoke Putunthan, or Chontal.¹ The modern Chontal area, however, is usually located west of the Laguna de Términos. It is proposed to publish facsimiles of the Chontal text and a transcription of the Spanish translation which accompanies it, with a minimum of comment so that linguists may have this important document available for study. The remainder of the monograph will deal with post-Conquest problems.

The *auto de fé* of Maní of 1562 and the problem of personal service in the 1570s relate to the most important phases of the career of Bishop Diego de Landa. The account of the Maní affair which will be based on the reports and investigations of Landa and Bishop Toral and on the residencia of Diego de Quijada, the alcalde mayor, will present the first thorough discussion of this most famous incident in the history of Yucatán in the second half of the sixteenth century. The controversy over personal service involved Landa because of his active support of Francisco Palomino, the defender of the Indians, who denounced the exploitation of the Indians by the encomenderos. Discussion of the problem is necessary, not only in fairness to Landa whose reputation, has suffered because of the Maní incident, but also as an introduction to one of the ever present problems of colonial administration in Yucatán, the problem of Indian labor.

Mr. Lewis Hanke, instructor in Harvard University, has a temporary part-time appointment under the Division for the purpose of continuing his studies in the juristic and theoretical phases of Spanish Indian policy in the sixteenth century. A grant from a research fund administered by Harvard University has made it possible for him to spend the summer in South America searching for unpublished materials relating to the subject of his investigations.

NOTES

1. A little more than 14 leagues farther toward Mexico, on the same sea-coast is another town called Tixchel of Indians better-looking and a little more polished and diligent than the Maya, who speak a different language called *Putunthan*, by another name *Chontal*, although in many words it agrees with Maya, and so knowing the one the other is easily understood" (Ponce 1932:347).

9.10.

RALPH L. ROYS

Study of Maya Colonial Documents

YB 34:148-150, 1935

Following the consideration of family documents and related papers [Chapter 9.7] a study has been made of various collections of Maya land documents, particularly the *Crónica de Calkini*, *Documentos de Tierras de Sotutá*, and *Títulos de Ebtún*. These, together with portions of the Pech and Xiu papers, constitute a documentary history of Indian land tenure from the native point of view during the colonial period.

In the winter and spring of 1935 a trip was made to Yucatán to locate and map the places cited in these papers and continue the task of tracing the frontiers of the former native states. Observations of the country, especially of the location of the more fertile areas, the watering places and evidences of pre-Conquest occupation aided in the understanding of the documents.

The purpose of this research is the application of Maya literature and the documentary sources written in that language to the history of the Yucatecan Maya. The method pursued is the comparative study of this material and its presentation in as adequate form as possible.

Colonial Maya documents contain much concerning the pre-Conquest Maya. They also bridge the gap between modern ethnological studies and the pre-Conquest data, much of which is still in a disordered state. In Maya literature, besides the chronicles and historical narratives there is a wealth of historical allusion in the prophecies, since it was believed that what occurred in a certain katun would recur in another katun of the same name and number. We have still to place many of these events chronologically and to coordinate them.

This, we believe, can be done by further documentary studies with the necessary aid of archaeology (especially ceramic sequences and architectural comparisons), ethnology and economics. The importance of the first seems axiomatic. That of economics has long been recognized in theory; but it is doubtful if the incompleteness of our knowledge was fully realized prior to recent ethnological and agricultural studies.

The importance of the social and political background of hereditary rank also seems obvious. One land agreement even states that "it is in order that our nobles may sustain themselves in time to come." Besides the "Indian *hidalgos*" and "native lords" recognized by Spanish law, we now find mentioned in the Maya documents other nobles, who did not enjoy this distinction. Most of these were local authorities, but the noble Dzul family who lived at Chichén Itzá at the beginning of the nineteenth century were, so far as we can learn, neither "*hidalgos*" nor officials.

Philosophical historians are turning to Maya history for analogies to support their conclusions as to the causes of the origin, growth and decline of civilizations. Such analogies, in a sphere so far removed from the currents of activity which swept over the Old World, should, when valid, go far to confirm a fundamental similarity in the development of peoples. The question arises whether the comparisons undertaken do not assume a certainty regarding Maya history which we do not as yet possess. Many facts are recorded, the sequence of which is insufficiently established, and their critical examination continues to be an important task.

Perhaps the best exposition of this aspect of the situation would be a concrete illustration. In the past, misleading analogies have been drawn from Old World history, but it must be admitted that our documentary material on Yucatecan Maya history appears to lend itself readily to one of the formulae of an eminent philosophical historian.¹

The Spaniards found a "composite society" fundamentally Maya but modified by Mexican ideas. This "affiliated civilization" might be traced as arising from the penetration of northern Yucatán, already an "outlying province" of the "apparent" Old Empire civilization, in the tenth century by intruders (an "external proletariat"?), who were the bearers of a Nahuatl culture and became the "dominant minority" in their new home. The result was a brilliant hybrid civilization. Late in the twelfth century occurred the "time of troubles" (a definite stage in the history of a civilization), during which Chichén Itzá was conquered by Mayapán. The "time of troubles" was succeeded by a "universal empire" (another normal development), in this case the domination by Mayapán of the entire

north, which finally ended in a revolution about 1450; and the country broke up into a number of warring independent states. The decline in civilization, which had already set in during the hegemony of Mayapán, became even more marked in the period which followed, and the conditions prescribed by the formula were not lacking. The "dominant minority," which was the repository of the culture, was separated from the "internal proletariat" by tradition and religious cult (the worship of Kukulcan), in which the latter did not share.

However, as we have already noted, our organized material is somewhat scanty and such an interpretation may be invalidated by new data and a coordination of the many uncorrelated facts which we already possess.

Maya culture did not cease with the Spanish Conquest, in spite of the important changes which ensued. Territorial government and religion were the institutions most rapidly affected, but an unconscious recognition of the old frontiers still exists and the modern ethnologist finds religious survivals today. The persistence of the Maya language, even among a large mestizo class, is very significant historically. The Indians were many and the Spaniards were few. Local government, even under Spanish supervision, continued in the hands of the Indians. Changes due to importations of European material culture came slowly; and agriculture, on the whole, still remains very much what it always was.

Any emphasis on the importance of the colonial Maya documents as a connecting link between the present and the more remote past should not obscure their value as a historical source for the period they actually cover. Even the most indispensable Spanish documents were, after all, written from the standpoint of our own European culture. Those written by the Indians in their own language show the native reaction to European ideas and institutions.

Maya documents of the Colonial period might be roughly divided into two classes. Those cited above are chiefly concerned with the relations of the Indians with one another. The much larger body of Maya texts discovered in the Seville archives by Mr. Scholes appear to deal with the relation between Indians and Spaniards. Both classes furnish much information about the Indians and each supplements the other. The advantage of record written by Indians for Indian readers is somewhat offset by the fact that many of the older documents exist only in the form of eighteenth and early nineteenth century copies. The Seville texts, on the other hand, are originals, which gives them more authority as linguistic documents. These rank with the Xiu papers as a source for the history of the Maya language during the last four centuries.

NOTES

1. In what follows we have departed somewhat from Professor Toynbee's (1934) application of his formula to Maya history.

9.11.

A. POGO

Maya Astronomy

YB 34:151–152, 1935

A survey of the contributions to the study of Maya chronology by Förstemann, Goodman, Thomas, Bowditch, Morley, Meinshausen, Spinden, Willson, Guthe, Teeple, Thompson, Martínez Hernández, Ludendorff, Palacios, Roys and Beyer, revealed the possibility of a new approach to the problem of correlating Maya and Christian dates.

In 1913, Meinshausen recognized that the pages 51 to 58 of the Dresden Codex contain a table of eclipse syzygies. Willson's attempt to derive a day-by-day correlation based on this table was unsuccessful; the posthumous publication, in 1924, of Willson's unfinished investigation conveyed, unfortunately, the impression that his negative results were final. Two erroneous assumptions underlying Willson's unfinished investigation ought to be mentioned here: first, that partial eclipses of the sun may be disregarded; and, second, that lunar eclipse's do not have to be considered; moreover, he overlooked the existence of the tenth "picture," at the bottom of page 58 of the Dresden Codex. An example of a part territory is quoted in the bibliogra-

phy accompanying this report; examples of lunar eclipses at Dresden "picture" intervals will be found in the table below.

In 1925, Teeple published his paper on the Glyphs C, D and E of the Supplementary Series of the inscriptions, a short and brilliant paper equaling in importance that of Meinshausen. Teeple's subsequent investigations of the lunar calendar of the Maya led him to consider the Dresden table of the eclipse syzygies, but he did not attempt to exhaust the correlation possibilities it offers; incidentally, he disregarded or overlooked, like Willson, the existence of the tenth, "picture."

A study of the periodicity of groups of eclipses had to be made, in order to bring out the correlation possibilities offered by the pages 51 to 58 of the Dresden Codex, on the one hand, and by the Supplementary Series, especially by Glyph C, of the inscriptions, on the other. Cylindrical diagrams based on the Mec (Maya eclipse cycle of 11,960 days = 405 lunations = 69 eclipse semesters = two double tzolkins) were-constructed; they permit us to trace the development of the ideas which led to the introduction of Supplementary Series and to the compilation of tables of eclipse syzygies. [Table 9.11.1] may be used as an example of the periodicity of groups of lunar eclipses which were visible in the Maya territory and occurred at Dresden "picture" intervals.

The total solar eclipse of -43 October 11.9, preceding the first group lunar eclipses of the table, was visible in the Maya territory, at sunset; the close conjunction with a Librae offered an opportunity of counting lunar cycles from a definite point in space as well as in time.

A preliminary survey of the correlations derived from groups of eclipse separated by Dresden "picture" intervals shows that a considerable amount of work will be needed in order to eliminate the spurious solutions; the final day-by-day correlation based on the Dresden table of eclipse syzygies and on the lunar

Table 9.11.1. Periodicity of Groups of Lunar Eclipses.

cycles recorded in the Supplementary Series of the inscriptions must be compatible with a simple interpretation of the Venus table of the Dresden Codex and of the Venus dates of the inscriptions.

9.12.

RALPH L. ROYS

Study of Maya Colonial Documents

YB 35:144–146, 1936

During the period under review Mr. Roys has been engaged in translating and editing for publication the *Títulos de Ebtún*, which are the archives of an old Indian town in eastern Yucatán. These papers have proved to value not only for the history of the immediate area, but also in their relation to other activities of the Division, for although Ebtún is situated Valladolid, its lands were scattered westward over a considerable area; and the *Títulos* contain information regarding a region, extending almost to Chichén Itzá in the north and along the ancient roadway to the ruins, of Yaxuná in the south. This includes, wholly or in part, the field of Dr. Redfield's and Alfonso Villa's ethnological study at Chan Kom (Redfield and Villa Rojas 1934), Dr. Shattuck's medical survey (Shattuck 1933), Dr. Steggerda's anthropometric work [Chapters 10.6 and 10.9], and Alfonso Villa's survey of the roadway (Villa Rojas 1934), not to mention the archaeological work at Chichén Itzá, practically on the edge of this area.

Consequently the *Títulos de Ebtún* furnish a valuable historical link between the pre-Conquest inhabitants and their descendants, who still constitute the bulk of the population of the region. The recent studies of the physical environment, mentality and daily life of the modern Maya have added considerably to our understanding of the significance of the archaeological remains; and if the present is to continue to illuminate the more remote past, it becomes increasingly important to trace the connection between them.

Photographs of the documents have kindly been loaned by the Peabody Museum of Harvard University, and Tulane University has permitted use of materials gathered during a preliminary study made under its auspices.

The original documents have also been consulted by Mr. Roys at Ebtún; and it has been possible to map nearly all the many localities cited in them with topo-

graphical data previously collected by Dr. Redfield, Alfonso Villa, the writer, supplemented by subsequent information from J. I. Rubio Mañé and Lawrence Roys.

The earliest Ebtún document, dated 1561, has been found in another collection, and the archives now at Ebtún begin in 1600 with a series of boundary treaties. These were concluded between Ebtún and four other associated southern Cupul towns, on one side, and their western neighbors of the former independent state of Sotutá on the other. Certain Sotutá documents will also be presented containing the Spanish translation of a boundary survey made by Nachi Cocom in 1545. As this date is believed to be the writing of Maya in European script, the original record was probably one of the *pinturas*, which we find mentioned, or a hieroglyphic map.

Among the 1,600 documents, some of the most interesting are those which tell in considerable detail of the scattered villages and hamlets whose rural population was concentrated in the five towns under Tomás López about the middle of the sixteenth century. Here occur the pagan names of the last inhabitants of these places and those of their Christian descendants in the towns. Ancient ruins are still to be found on a large number of these sites, or "old towns" as they are called in the documents.

There are indications that land ownership in such rural settlements may have been largely a family affair. This is of interest in view of Gaspar Antonio's statement that lands were held in common. Family ownership of land used for farming certainly goes back to 1561 in some cases, and how the presumed change from communal ownership came about is not yet entirely clear.

Sometimes, either by direct transfer or through a temporary Spanish owner as intermediary, land passed from one town to another. This usually caused trouble. In the case of the Tontzimin tract near Chan Kom, its sale by an Ebtún man to a resident of Cuncunul in 1638 resulted in a series of bitter disputes and lawsuits which ended only in 1820.

The many land transfers and surveys constitute in themselves a documentary history of the town of Ebtún. We find individual and communal ownership of lands existing side by side. Although the higher municipal offices were usually held by a limited number of prosperous land-owning families, it was always the policy of the town to increase the communal holdings, apparently for the benefit of the poorer inhabitants.

Frequently these documents tell how and from whom the vendor acquired the property, whether by purchase, gift, or inheritance. Sometimes the reason for the sale was a famine, when people had gone to the forest to live on wild fruits and roots. More often it was due to poverty arising from sickness or old age,

especially when the owner had neither sons nor sons-law to cultivate the land. Occasionally the vendor invokes such penalties as fine and flogging, if he should ever afterward question the validity of sale. In a few cases there is even information as to how the buyer acquired the purchase money.

Among these papers are a number of wills listing the possessions of more well-to-do members of the community. Bequests were mostly of beehives, tools, household paraphernalia, forest lands, fruit-trees, town lots the home of the testator. Lands were often bequeathed as joint property of all the children, but we sometimes later find them subdivided or the various interests bought up by one or two of the heirs. Few horses and practically no cattle were willed. Cattle raising, with the resulting damage to unfenced crops, was very unpopular, although it was extensively practiced by Spanish land-owners.

Other documents are Maya translations of proclamations by the governor, a few complaints of ill treatment by Spaniards, records of purchase of municipal supplies and commitments to jail, usually for wife-beating or disrespect to the local authorities.

Among the people of the region today, Ebtún is noted as the mother of colonies; and it was due to her land policy that a number of villages, Chan Kom among them, have since sprung up on what were formerly the communal lands of this town.

9.13.

FRANCE V. SCHOLES

History of Yucatán

YB 35:150–151, 1936

The documentary research for the monograph on the cacicazgo of Acalán-Tixchel has been completed, and it is hoped that the manuscript will be finished by the end of 1936. This volume will contain: 1. The history of the *cacicazgo* over a period of 90 years beginning with the of Cortés to Honduras and ending with the removal of the Ichbalche, Tzuctoc, Ichmachich, Chunhas, etc., to the region of Sahcabchen in 1615; 2. Facsimile reproduction of the Chontal text describing the history and services of the caciques of Acalán-Tixchel; 3. An annotated Spanish translation of this text; and 4. A brief statement concerning the aborigi-

nal history, ethnography, and linguistics of the area comprising the cacicazgo. Miss Adams, Mr. Roys, and Mr. Scholes are collaborating on this work.

Although this monograph will throw a flood of light on the Acalán-Tixchel area, the lack of adequate geographical and archaeological information concerning the region makes it difficult to form definite conclusions on essential points. Perhaps no part of Spanish North America has been less explored in recent times than this area, which lies east of the Usumacinta and south of Laguna de Términos. An expedition of reconnaissance archaeological and geographical purposes is greatly needed.

Considerable progress has been made on the documents dealing with life of Fray Diego de Landa and the beginnings of the Inquisition in Yucatán. The materials from the Archivo General de Indias in Seville, especially those which relate to Landa's investigation of Indian idolatry in 1562, are being thoroughly studied by Miss Adams and Mr. Scholes, and Sr. Rubio Mañé has started work on the Inquisition papers in the Archivo General de la Nación in Mexico City. By the end of December 1936, the documentary work prior to 1571, when a formal tribunal of the Holy Office was established in Mexico, should be completed.

This monograph and the study of the materials dealing with Landa's career in Yucatán during the 1570s will pave the way for a needed biographical sketch of the bishop. Such a study will be prepared by Mr. Scholes as part of a volume containing an annotated translation of Landa's *Relación de las cosas de Yucatán* to be published by Professor A. M. Tozzer under the auspices of the Peabody Museum.

Materials are accumulating for the history of the encomienda in Yucatán; the first section covering the beginnings of this institution prior to 1550 is rapidly taking form.

Sr. Rubio Mañé has continued his work in the local archives of Yucatán. In October 1935, Mr. Scholes spent a week with him in Mérida in conference concerning phases of his investigations. The survey of the parish records in Mérida and Campeche has been completed, and considerable time has been spent in searching through the records in other towns in connection with investigations for Mr. Roys and Dr. Morley. At the request of Mr. Scholes a test study was made of the first volume of the marriage records of the Negro parish in Mérida, covering the years 1568 to 1610, in order to obtain information concerning the intermarriage of Indians and Negroes. Sr. Rubio Mañé summarized his findings as follows: 1. Marriages: Negroes with Negroes, 19; Negroes with Mulattos, 16; Negroes with Indians, 42; Mulattoes with Indians, 27; Mulattoes with Mulattoes, 11; 2. Number of Individuals Mentioned, Slaves: Negroes, 105; Mulattoes, 29–134. Free: Negroes,

8; Mulattoes, 19–27; and, 3. Number of slaves mentioned, 65; average number of slaves per owner, 2+.

These investigations in the records of the Negro parish will be continued when Sr. Rubio Mañé returns to Yucatán at the end of 1936. It is obvious that they will not provide a complete picture concerning the Negro and Mulatto population of the province, but they should provide valuable data concerning the amount and rate of mixture of the Negro and Indian races.

During the past year Dr. Chamberlain's work on the Spanish archive materials for the life and times of Montejo was practically completed. In June 1936, he left for Mexico and Central America, where he will explore the local collections for documents on the history of Central America prior to 1550. In view of the fact that the career of Montejo in America extended to 1550 and was so intimately related to the whole Maya region, it is hoped that Dr. Chamberlain may be able to expand his work on the Adelantado into a general history of the conquest of the region from Tabasco to the Río de Ulúa, roughly the entire Maya culture area. It is also expected that as a result of his investigations in Guatemala the Institution will have definite information concerning the general content and volume of the local archives, on the basis of which a decision may be reached with regard to further historical research in the Guatemala area.

Dr. Hanke has carried forward his research on theoretical phases of Indian legislation and policy in the sixteenth century.

9.14.

ALFRED V. KIDDER

History of Yucatán

YB 36:155–157, 1937

Dr. Robert S. Chamberlain, who is preparing a detailed study of the conquest of the entire Maya area, spent the summer of 1936 in Yucatán and Guatemala carrying on investigations in the local archives. In March 1937 he returned to Central America to continue his investigations. The reorganization of the archives of Guatemala now in progress made it impossible to search certain local collections, but except for these Dr. Chamberlain's work in the Guatemala archives has been completed. A rapid survey of the principal archives of Honduras and El Salvador has also been

made. Although the materials for the period of the Conquest in these collections are not numerous, important documents have been found that fill in lacunae in the papers in Seville.

The archives of Guatemala City are rich in materials for the later colonial period, and Dr. Chamberlain has prepared a brief report dealing with archival organization at the present time and indicating the general nature of the contents of the individual archives. This report will be extremely useful for students of the local history of Guatemala and for those interested in general problems of Spanish colonial policy and administration in the New World. It will be printed in the *Handbook of Latin American Studies* for 1937.

During his stay in Yucatán in the spring of 1937 Dr. Chamberlain spent some time at Chichén Itzá in conference with Dr. Morley and Mr. Roys, and together with Mr. Roys he made a brief reconnaissance of the area east of Tizimín. At the site of Dzoonot Aké ruins were found. Information was also received which should be useful in identifying the site of Chuac-há.

In April Dr. Chamberlain and Mr. Ruppert visited Tixchel near Sabanquy. Tixchel was an important pre-Conquest site resettled during the second half of the sixteenth century by groups of Chontals from the Acalán area. The exact location of the village of Acalán is still undetermined. Documents of the sixteenth century clearly indicate that the Candelaria drainage formed an important part of the cacicazgo of Acalán-Tixchel. Chamberlain and Ruppert made a short trip up the Candelaria. Although ruins exist at several points on the middle and upper parts of the river, none could be identified as Acalán.

Dr. Chamberlain will spend the summer of 1937 working in the archives of Mexico City. He also hopes to visit Chiapas, before he returns to the United States in the autumn.

Sr. J. Ignacio I. Rubio Mañé has spent the year 1936–37 in Mexico City carrying on investigations in the Archivo General y Público de la Nación and in the Biblioteca Nacional. The Inquisition papers in the Archivo General contain a mass of Yucatán material, and copies or extracts have been made of all the documents ante 1580. These data will be incorporated in the volume on the life and times of Fray Diego de Landa being prepared under the direction of Mr. Scholes.

The Sección de Civil of the Archivo General contains 2,302 volumes of uncatalogued papers for the entire district administered by the audiencia of Mexico. They consist of suits before the audiencia, residencias, reports, etc., that are of great value for every phase of the administrative history of New Spain. Up to the present time Sr. Rubio Mañé has examined 1,250 volumes in this series and has found important items for the history of Yucatán. The most valuable finds to date

are: 1. Records of the Palacios visita in the 1580s, and 2. Documents pertaining to the Yucatán phases of the visita of New Spain by Gálvez in the eighteenth century. In addition to these outstanding groups of papers there is a mass of material on encomiendas, Indian labor, and land administration. The Sección de Tierras, consisting of 3,692 volumes, of which 2,971 have been catalogued, supplements the materials in the Sección de Civil. Most of the Yucatán documents, as indicated by the catalogue, deal with the eighteenth and nineteenth centuries.

In the Sección de Historia items have been found dealing with the population of Yucatán in the late eighteenth century and with the organization of schools during the same period. In the Biblioteca Nacional the most important find was a report on general conditions in Yucatán made as the result of the visita of the province in the time of Gálvez. This document which supplements similar papers in the Sección de Civil, is being published by Sr. Rubio Mañé in the *Diario de Yucatán*.

Mr. Scholes and Miss Adams have been engaged in preparing several groups of materials for publication. In collaboration with Sr. D. Carlos Menéndez, editor of the *Diario de Yucatán*, a volume of documents on the history of Yucatán, 1550–61, has been published, and a second volume of documents on the organization of the Church and the missions, 1560–1610, is now in press. Two volumes of documents dealing with the administration of the alcalde mayor Don Diego de Quijada, 1561–65, and with the famous *auto de fé* of 1562 will be ready for the press in October. These volumes will provide the documentary background for the essay on the life and times of Fray Diego de Landa to be issued in conjunction with the translation of Landa's *Relación de las cosas de Yucatán* to be published by Professor A. M. Tozzer, of the Peabody Museum of Harvard University.

Work on the Acalán-Tixchel volume was postponed pending the report of the reconnaissance of Dr. Chamberlain and Mr. Ruppert up the Candelaria River. It is now clear that a thorough exploration of the area south of Términos will be necessary before the Acalán question can be finally solved. Inasmuch as such a reconnaissance will not be made for some time, the volume on the cacicazgo of Acalán-Tixchel will be pushed to completion during the coming year.

Dr. Chamberlain and Mr. Scholes are collaborating on a paper on population problems in Yucatán prior to 1550 which should be completed within a few months. Progress has been made on the first section of the study of the encomienda in Yucatán.

All these documentary publications and monographs are preliminary to the first two volumes of the general history of Yucatán, 1550–1810, which forms

the major objective of the researches of Mr. Scholes, Miss Adams, and Sr. Rubio Mañé. But the discovery by Sr. Rubio Mañé of such a large mass of documentary material in the archives of Mexico means that a thorough going examination of these papers will be necessary before this larger study of Hispano-Indian society and administration in Yucatán can be put in final form.

9.15.

RALPH L. ROYS

Study of Maya Colonial Documents

YB 36:157, 1937

Much of the period under review has been spent by Mr. Roys in completing the translation and annotation of the papers found in the municipal archives of Ebtún in eastern Yucatán [Chapter 9.12]. An introduction has been written summarizing the historical and ethnological material contained in these documents and reviewing the social, economic, and local political development of this region during the Spanish colonial period.

In collaboration with Mr. Scholes, a preliminary study of the Acalán-Tixchel area has been made, also annotations to the Spanish version of the history and service record of the caciques of this region [Chapter 9.12] in the light of a comparison of this document with the original Chontal text.

During the late winter and spring of 1937 Mr. Roys was in Yucatán. Accompanied by Dr. Steggerda, he made a journey along the border of the southern Cupul area and the former Province of Cochuah. The line was found to extend from a point about 10 km south of the west end of the ancient Cobá-Yaxuná road in an easterly and southeasterly direction.

This old frontier was located from watering places and other sites hitherto unmapped but cited in the early post-Columbian Maya documents. Many portions of the former boundaries separating the Provinces of Ah Canul, Maní, Sotutá, and the Cupuls are remembered by the present-day Indians; but consciousness of a geographical division between the southern Cupul and the Cochuah areas no longer exists among the present Indians living in this region. During the War of the Castes the native rebels occupied this part of the Cochuah area for a considerable time. Finally,

when the remainder of them retreated to the forests of Quintana Roo, the district was settled by immigrants from the neighborhood of Valladolid. People interviewed at Chikindzonot and Ekpedz, formerly important Cochuah towns, had come from near Valladolid and were apparently unaware that their new homes were in what had formerly been a separate territorial entity.

Some time was spent at Chicxulub and Yaxkukul in northwestern Yucatán, in order to locate the boundaries of their lands. These are described in the sixteenth century Maya manuscripts of the Pech family, photographs of which were secured by Dr. Morley during the past year. Although the chief interest of these papers lies in the important historical material which they contain, they were primarily land documents; and an adequate presentation of them is hardly possible without a topographical knowledge of the territory which they cover.

This district is now given over to the cultivation of sisal hemp, and the old agricultural life, so much in evidence in many parts of Yucatán, has greatly changed. Maya is still the language of most of the people, but a considerable Spanish admixture is to be seen in the population. There is even an occasional structure of sawn lumber among the Maya pole and thatch houses and the stone buildings of Spanish type.

9.16.

ALFRED V. KIDDER

History of Yucatán

YB 37:166–169, 1938

During the past year Sr. J. Ignacio Rubio Mañé has continued his search for materials on the colonial history of Yucatán in the Archivo General de la Nación in Mexico City. The volume-by-volume survey of the *Ramo de civil*, which had progressed as far as volume 1,250 by July 1, 1937, was carried through to volume 2,302, the last in the series. The uncataloged part of the *Ramo de tierras*, volumes 2,972 to 3,623, has also been searched. In these two ramos a mass of new material for the history of Yucatán, especially for the eighteenth century, has been found. The documents deal with governmental organization and administrative policy, ecclesiastical affairs, Indian administration, encomiendas, the economic history of the province, suits over

lands, and private business transactions. A series of expedientes relating to the abolition of the encomienda system in 1785–86 deserves special notice. Photographic reproductions of several important items have already been made and others will be reproduced during the year 1938–39. After completing his work on the above-mentioned series, Sr. Rubio Mañé started a survey of a number of less extensive series, such as Arzobispos y obispos, Real audiencia, Expolios, Real acuerdo, etc. He will be engaged in this work during the greater part of the coming year.

Dr. Robert S. Chamberlain spent two months (July 17–September 24, 1937) in Mexico City, after completing his investigations in the archives of Guatemala, El Salvador, and Honduras. During this time he examined several sections of the Archivo General de la Nación, especially the papers of the Hospital de Jesús, as well as parts of the Archivo de Notarios, the Archivo del Ayuntamiento, and the Cathedral archive. Unfortunately, very few documents pertinent to his investigations on the history of the conquest of the Maya area were found.

Since his return to the United States in October 1937, Dr. Chamberlain has been engaged in the preparation of certain materials for publication. A résumé of the history of the conquest of Yucatán, based on the more extensive and detailed sections of his projected history of the conquest of the Maya area, has been largely completed. This will be incorporated in the introductory section of the work on the life and times of Fray Diego de Landa being prepared by Mr. Scholes. Dr. Chamberlain has also written a preliminary draft of a chapter on the exploration and conquest of the Acalán-Tixchel area which will form part of the larger work on the cacicazgo of Acalán Tixchel on which Mr. Roys and Mr. Scholes are also collaborating. During the last three months of the year 1937–38, Dr. Chamberlain devoted most of his time to the preparation of a short monograph on the Castilian origin of the encomienda system, which should be ready for publication by the autumn of 1938.

Mr. France V. Scholes and Miss Eleanor B. Adams gave most of their time during the past year to the preparation of two volumes on the administration of Don Diego Quijada, who served as alcalde mayor of Yucatán from 1561 to 1565. It was hoped that the manuscript of this work would be finished before the end of 1937, but the decision to add a considerable number of documents to the series as originally planned made it necessary to carry the work over into 1938. These volumes, which are now in press, will contain 85 documents and a lengthy introduction. The latter will describe the development of Yucatán from 1550 to 1561, the beginnings of the Quijada regime, the famous investigation of Indian idolatry made by Quijada and

Fray Diego de Landa in 1562, the increasing resentment inspired by Quijada's government, especially his attempt to abolish burden bearing, the residencia of the alcalde mayor, and the final vindication of Landa for his share in the unhappy events of 1562. As stated in the *Year Book* for 1937 [Chapter 9.16], the material published in these volumes will provide the documentary basis of part of the work on the life and times of Landa being prepared by Mr. Scholes with the collaboration of Dr. Chamberlain, Miss Adams, and Sr. Rubio Mañé.

Mr. Scholes spent part of November and December 1937 in Mexico City in conference with Sr. Rubio Mañé and in negotiations with the editor and publisher of the Biblioteca histórica mexicana series, in which the two volumes on Quijada are to appear. Late in June 1938, Miss Adams left for Mexico City, where she will spend several months carrying on investigations in the Archivo General de la Nación in collaboration with Sr. Rubio Mañé.

During the past year volumes 2 and 3 of the *Documentos para la historia de Yucatán*, edited by Mr. Scholes, Sr. Carlos R. Menéndez, Sr. Rubio Mañé, and Miss Adams were published. Volume 2 contains a series of 44 documents illustrating ecclesiastical organization, and the development of the missions from 1560 to 1610. Volume 3 contains a report on general conditions in Yucatán in 1766 entitled *Discurso sobre la constitución de las Provincias de Yucatán y Campeche*. Included in the volume are two appendices, the first describing the government of Campeche in 1746, the second being a census of Yucatán for 1790. In the *Handbook of Latin American Studies*, 1936, pp. 387–432, Dr. Chamberlain published "A report on colonial materials in the government archives of Guatemala City."

Mr. R. L. Roys devoted the first part of the period under review to revision and completion of maps of the prehistoric Yucatecan Maya states, or so-called provinces, of the Cupuls, Sotutá, and Maní, from topographical material gathered during the spring of 1937 and described in a previous report [Chapter 9.15]. The first two will appear in *The Titles of Ebtún* (Roys 1939), and the last will accompany the publications of the Xiu probanzas and related documents.

The two series of documents mentioned above constitute a general history, from the native point of view, from the Spanish Conquest down to the period covered by the ethnological studies of the modern Maya. These papers deal principally with the more material facts of existence and may be supplemented in course of time by a study of native intellectual and religious life during the colonial period. Some of the material for this will be found in the mixture of Spanish astrology and Maya science, both of which were closely bound up with religious ideas, recorded in the Maya language in the later Books of Chilam Balam.

At the present time, however, it has seemed desirable to inquire more closely into what the white man found when he arrived in the various parts of the Maya area: the state of affairs at the time of this contact, as distinguished from subsequent developments influenced by European culture, on one hand, and previous conditions no longer existing but disclosed by archaeological investigation, on the other.

There are some indications that more or less similar conditions may well have existed for at least three centuries prior to the Conquest in the highlands of Guatemala and perhaps considerably longer in regions between that area and Yucatán. In Yucatán, however, there was a great political and social revolution about the middle of the fifteenth century. Its more conspicuous effects were the breaking up of a centralized government and the abandonment of the stone-vaulted buildings, which were replaced by more or less perishable structures with thatched roofs. In the Old World such a decline in architecture has been either more gradual or the result of invasion and in the prayers of the modern native herb doctors.

Now that photographs of the oldest copies of the Pech documents have been acquired, Mr. Roys has undertaken a new transcription and annotated translation of these papers. They consist of two collections, one from the town of Chicxulub and the other from Yaxkukul.

These towns formed the subject of a topographical study [Chapter 9.15] in 1937. Brinton published the text and translation of the most important Chicxulub document in 1882, and Martínez' did the same for all the Yaxkukul papers in 1926, but did not include the official Spanish translation made in 1769.

These important documents are probably the earliest Maya narratives written in European script that have come down to us and include immigration by less cultured peoples, which was not the case in Yucatán at this time. Much of the previous state of affairs, which reminds us in some respects of the conditions in the highlands of Guatemala at the time of the Conquest, was still a matter of general knowledge when the Spaniards conquered Yucatán, so it may be possible to trace the causes and effects of this famous crisis in aboriginal American history.

New documents discovered by Mr. Scholes in the archives of Mexico and Spain have not only added to the sum of our knowledge, but also required a fresh examination and reinterpretation by Mr. Roys of historical sources which have long been known.

For the *Report and census of the Indians of Cozumel, 1570*, already mentioned in a previous report [Chapter 9.7], the introduction has been enlarged and rewritten from the study of a considerable number of related documents furnished by Mr. Scholes.

An ethnological study has also been made by Mr. Roys of the proceedings of Landa's inquisition in 1565, which furnishes a very appreciable amount of new material. In Mr. Roys' opinion, the human sacrifices and other pagan ceremonies performed in Christian churches during the second decade after the Conquest suggest that temple ritual had continued to retain much of its importance; in spite of the decline of temple architecture and the prominent part played by the private oratory.

Sacrifices were made to bring rain and favorable weather for the crops, to avoid recurrence of hurricanes, and for the benefit of ailing chiefs. It is of especial interest to learn that the *cenote* cult was not confined to Chichén Itzá. While some victims were still taken to that site, in numerous cases the bodies were cast into local cenotes in the Sotutá district. Although Christian influences are already seen in the crucifixion of some victims, a logical development since the cross was a Maya religious symbol, the details of other forms of sacrifice are invaluable to the ethnologist.

We are introduced here to a new category of Maya deities, the gods of the different lineages or name groups. The greatest of these, Zacalpuc, we already know as one of the early Mexican invaders of Yucatán and the head of a lineage. Indeed, he still figures accounts of the Spanish Conquest by two native chiefs who were allies of the Spaniards. In consideration of Dr. Chamberlain's current study (if the conquest of Yucatán and a number of later documents from the Pech are discovered by Mr. Scholes in the Archives at Seville, the publication of the entire series of the Chicxulub and Yaxkukul papers, with new annotations seems desirable at this time.

from native and Spanish chronicles such information regarding the social, economic, and religious life of the Maya as will aid in explaining many puzzling aspects of the archaeological finds. The second, and this of course is in the historian's own province, is to reconstruct as fully as possible the events which shaped the destiny of the Maya from the Conquest to the present day. The third is to erect for the ethnologists and other students of the living Maya the same sort of background that the archaeologist provides for the historian.

The Division entered the documentary field in 1931 with the appointment of F. V. Scholes. With him have since been associated R. S. Chamberlain, Eleanor B. Adams, and the Mexican scholar J. I. Rubio Mañé; while R. L. Roys has devoted himself to the translation and interpretation of the Maya's own literature, the so-called Books of Chilam Balam.

The history of the Maya from the period of the Spanish Conquest to the present time has a definite importance not only in relation to other phases of the Yucatán Project, but also for the general field of Latin American history. The significant problems of the history of those Latin American countries where the Indian has survived in any considerable numbers are essentially social problems, Latin America may be regarded as a laboratory in which vast cultural and sociological experiments have been carried out. Aboriginal civilizations, varying in achievement, flourished over a period of many centuries in several parts of the Latin American area. In the sixteenth century these civilizations were submitted to a rude shock by the European conquest, but neither the Indian nor his culture was wholly destroyed. The Indian survived, and today Indian blood is a predominant strain in the population of many Latin American countries. Elements of aboriginal culture also survived in language and old folkways. To these have been added many characteristics of Hispanic culture. The four centuries since the conquest have thus been characterized by a long process of fusion, conflict, and amalgamation, resulting in the evolution of a Hispano-Indian civilization, varying with geographic conditions, the virility of the old Indian culture, and the policies and prowess of the conquering race. The survival of the Indian and of modified phases of his culture is the basis of many of the major modern Latin American problems of political and social significance, such as the distribution of wealth, land tenure, general economic progress, education, and public health. In recent years, moreover, the art and literature of Latin America, especially of Mexico, have been vitally affected by the same influence. The study of Latin American history is, therefore, essentially a study of the fusion and conflict of cultures. A sympathetic understanding of these processes

9.17.

ALFRED V. KIDDER

History of Yucatán

YB 38:248-253, 1939

The Division's archaeological activities, already discussed, have added much to our knowledge of the Maya of ancient times. To carry their story another step farther is the task of the documentary historians. Their work has triple aims. One of these is to glean

is essential for any just estimate of contemporary Latin American life.

The sources for historical research upon the Maya are partly printed: accounts of the discovery and Conquest, histories of the Colonial period, and works dealing in a more general way with Spanish policy toward the Indians. But by far the greater amount of material still lies buried in the archives of Yucatán, Mexico City, and Guatemala, and particularly in the enormous repository of the Archive of the Indies at Seville. The word "buried" is used advisedly, for not only are the desired papers often difficult of access, but pertinent facts must be gleaned from countless thousands of manuscripts: records of the church and of the courts, tribute rolls, and the multitudinous reports of officials. From this mass of at first sight mostly sterile, routine stuff come not only solid factual data, but also flashing side lights which often illuminate the life and events of the times more clearly than do the pages of the formal histories.

A preliminary survey of the archives of Yucatán made by Mr. Scholes in 1931 revealed that a large part of the local papers, especially for the Colonial period, had apparently been lost or destroyed. Consequently it was decided to postpone a detailed study of the local documents until considerable work had been done in the central archives of Spain and Mexico. Mr. Scholes and Dr. Chamberlain spent two and a half years (1932–34) in Spain, and Dr. Chamberlain has also worked in the archives of Mexico City, Guatemala, and Salvador. In 1936 Sr. Rubio Mañé started a survey of the Yucatán materials in the Archivo General de la Nación in Mexico City. Photostats and Leica films of important documents relating to the Maya have been brought back for study. These are gradually being digested, materials of value to other scholars are passed on to them, and information is steadily accruing for the two major histories which will be produced by the Division: that of Yucatán by Mr. Scholes and that of the conquest of Central America by Dr. Chamberlain.

During the past year Sr. Rubio Mañé continued his investigations in the Archivo General de la Nación in Mexico City, and Miss Adams, who spent several months (July 1938–May 1939) in Mexico, also gave part of her time to research in the same archive. Most of the important *ramos*, or sections, open to investigators have now been searched for documents on the Colonial history of Yucatán. During the year 1939–40 Sr. Rubio Mañé will assist in the cataloguing of a large section that heretofore has been closed to investigators, and it is expected that additional materials on the history of the province will be found in this collection.

The local Yucatán collections have not been entirely neglected, however, during the past eight years. In 1935–36 Sr. Rubio Mañé made a survey of the

Archivo de Protocolos in Mérida and the parish records in Mérida and Campeche. Mr. Roys and Sr. Rubio Mañé have also worked in the parish archives of some of the Indian towns. During the summer of 1936 Dr. Chamberlain examined materials in the Biblioteca Çepeda and the Museo Arqueológico e Histórico in Mérida.

In the Archivo de Protocolos in Mérida, which contains registers of deeds, mortgages, wills, etc., nothing remains for the period prior to 1689. Beginning with the eighteenth century, however, this archive is fairly complete and will be the source of much information concerning the economic history of Yucatán during the past 200 years. The parish records of Mérida have been preserved in almost complete form; those of Campeche, although less complete, are fairly extensive. These documents have little value, however for the study of political and administrative history.

During February, March, and April of the past year Mr. Scholes, assisted by his nephew, Mr. W. V. Scholes, made a survey of the Archivo General de Estado and the documents in the Museo Arqueológico e Histórico in Mérida.

The Archivo General del Estado contains several thousand bundles and volumes. These papers, formerly kept in the Museo Arqueológico e Histórico, have recently been transferred to another building and set up as a separate archive. At the time of Mr. Scholes' visit last spring the newly appointed custodian than had not been able to begin arduous task of classification, but mission to make a search for colonial materials was granted. It was hoped that this collection, the official papers of the province and state of Yucatán, would contain local administrative documents of the Colonial governors and other local officers, especially for the sixteenth and seventeenth centuries, but this hope was not justified. Search by the Messrs. Scholes revealed only a very small amount of Colonial material, dating from the last half century of Spanish period. One group of papers, however, is worthy of special notice, *viz.*, an almost complete town-by-town census of the province for the years 1809–11. These census reports and a few other documents were photographed. For the nineteenth century the collection is remarkably complete, with long series of administrative decrees, correspondence of local officials, special reports, journals of the local legislative bodies, vital statistics, etc. These materials will provide the documentary basis for the history of Yucatán since Independence.

The colonial archives of the cabildo of Mérida are now kept in the Museo Arqueológico e Histórico. Unfortunately the documents of the sixteenth and seventeenth centuries have been lost or destroyed. The earliest cabildo books begin with the decade of the 1740s, and for the remainder of the colonial period the series is fairly complete. The Museo is sole custodian of an

important collection of registers of military decrees, local correspondence, and other administrative papers for the last two decades of the colonial period and the first half century after independence. During the past spring photographs were obtained of a large part of the cabildo documents for the eighteenth century.

During the past spring inquiry was made concerning the archives of Valladolid. Only a few documents (all of recent times) were found in the Ayuntamiento, and it appears that the Colonial archives and most of the papers for the nineteenth century have been destroyed. There is also little hope of finding important early administrative documents in Campeche.

The fragmentary character of the local elections increases the importance of Spanish and Mexican archives as the principal storehouses of documents on the colonial history of Yucatán. We are also brought face to face with certain definite problems. Some of the most important aspects of the Colonial history of the province, as of other parts of Spanish America, are those relating to Indian labor, land tenure, and the government of Indian towns. For these questions, local administrative documents would naturally constitute one of the principal sources of information. Unfortunately the major local collections that have been examined contain very little material of this kind for the sixteenth and seventeenth centuries. With regard to land tenure the gap can be filled in part by the hacienda papers in private hands, some of which go back to the sixteenth century. Mr. Scholes and Sr. Rubio Mañé have been permitted to examine and copy certain documents of this kind. During the past spring photographs were also obtained of a privately owned document of great historical value for the Calkini area. And there is always the possibility that some new collection of administrative papers may be found in Mérida, although the fragmentary character of the archives that have been surveyed offers little hope that early documents have been preserved in considerable quantity. For many problems, we must turn to the archives of Mexico, where early administrative papers for other parts of New Spain are available, and generalize, at least in part, on the basis of practice in these areas. Study of administrative practice in other areas would have been important in any case, in order to form valid conclusions concerning Yucatán problems and as a means of providing bases of comparison; for the history of Yucatán during the Colonial period must be projected against the background of general Spanish colonial policy and achievement. But in view of the present lack of early administrative documents available in Yucatán, this procedure has become a positive necessity.

To this end Mr. Scholes and his assistant spent several weeks in Mexico City in May, June, and July,

during which time investigations were carried on in the Archivo General de la Nación in collaboration with Sr. Rubio Mañé. Copies were made of numerous documents illustrating administrative practice in New Spain with regard to Indian labor, the functions of local Indian officials, land tenure, stock raising, local industries, the social status of Indians, mestizos, Negroes, etc.

During the past year two volumes of documents, edited by Mr. Scholes and Miss Adams, were published in Mexico City. These volumes, entitled *Don Diego Quijada, alcalde mayor de Yucatán, 1561-65*, contain selected parts of the contemporary records of the investigation of idolatry made by Fray Diego de Landa in 1562, letters describing conditions in the province, documents on the problem of forced Indian labor, and official papers relating to the residencia of Quijada. A brief résumé of the idolatry proceedings was also embodied in a paper written by Mr. Scholes and Mr. Roys.

Conditions in Spain made it necessary for Dr. Chamberlain to postpone his trip to Seville to complete his investigations relating to the conquest of the Maya area. During the past year, therefore, he has carried on a series of lesser investigations. He has published a short study on the Castilian origins of the encomienda system and a paper on the concept of the *señor natural* in Spanish and Indian law. In February he gave a lecture in Washington on Spanish methods of colonization as illustrated by the history of Yucatán. The text of this lecture was published in the *Scientific Monthly*. At the end of the year 1938-39 he was at work on a survey of pre-Conquest tribute systems.

In the autumn of 1938 Dr. Hanke resumed his investigations on theoretical aspects of Spanish colonial policy and administration in the sixteenth century, after an interval of 20 months during which he held appointment as research fellow of the Social Science Research Council. During the past spring he was appointed Director of the Hispanic Foundation of the Library of Congress.

During the period under review Dr. Morley and Mr. Roys have continued their research on the Xiu, the pre-Spanish lords of the great New Empire city of Uxmal, who retained for many years after the Conquest the status of nobles and whose descendants are still living in Yucatán. The story of this family through the centuries illustrates, and in some ways epitomizes, the whole later career of the Yucatecan Maya.

Mr. Roys spent the late winter and the spring of 1939 in Yucatán working with Dr. Morley, gathering linguistic data, and, alone and in company with Mr. Scholes, visiting various parts of the peninsula in order to locate and study the environmental conditions at a number of sites which were of importance during the Conquest and in the days of colonization.

From Motul, as headquarters, a number of towns were visited in the east portion of the former province of Ceh Pech. Like the western part of this province, the country around Chicxul and Yaxkukul, which had previously been examined [Chapter 9.14], the rocky land is flat or slightly rolling and now given over to the cultivation of sisal hemp. Little maize is raised, and where it is, the production is low; so it seems not unlikely that the prosperity and thick population of this region at the time of the Conquest should be ascribed to salt production, fisheries; and commerce. There is a handsome Spanish colonial church in every town, but unlike the western part of the province, where ruins are frequent, no pre-Spanish remains were seen except at Uci, a short distance north of Motul. Here, from the top of the highest pyramid, seven other mounds, large and small, could be counted, and there are two cenotes in the center of the group. A survey was also made of a part of the northern coast of the province of Cehech. The site of Maxtunil, which figures prominently in the Pech papers and as a town of about 2500 inhabitants in 1549, could not be located; but the long, narrow lagoon inside the sand dunes was followed with considerable interest, as we believe it to have been an important commercial route in former times.

Mr. Roys also made a journey in search of the former town of Hunacti, a capital of what appears to have been a semi-independent subdivision of the Xiu state, but lying outside the province of Maní proper. It was governed by a member of the Xiu family, an intimate associate of the last Xiu ruler. This figures in the Chumayel migration narrative, one of the Maya chronicles, the Maní land treaty of 1557, and Landa's inquisition proceedings in 1562, and then completely disappears from all the records. Inquiries during previous years at Tekax, Peto, and Tadziu had elicited no information, and it was decided to go to Tixmeuac and start from there in the direction indicated by the Chumayel narrative. No one at Tixmeuac had ever heard the name, but some 6 km to the northeast a group of out 15 platforms and the ruins of a Spanish church were found. These are generally known as the ruins of Sisbic, but local Indian farmers stated that among themselves the place always been called *Hunacti*.

From Tixmeuac a number of border sites of the province of Maní, mentioned in the treaty of 1557 and shown in the native maps, or diagrams, of the province, were located and plotted. Several of these were found to be Maya ruins, which are fairly numerous in this region.

With Mr. Scholes a visit was made to Calotunil, which, together with Peto and Tzucacab, formed another semi-independent subdivision of the Xiu state. A site of this name near Catmis sugar plantation had

been reported to Sr. Rubio Mañé. Catmis, when visited, was found to correspond to what we know of this Calotmul; there are several Calotmuls in Yucatán. Here, too, was found a Spanish church and cistern among a large group of ancient mounds.

The former site of Tixel was also visited [Chapter 9.14]. It was situated on an estuary of Laguna de Términos and commanded the principal commercial route between Mexico and Yucatán in pre-Spanish times. The place figures prominently in the Paxbolon relación [Chapter 9.7 and 9.10]. The Chontal-speaking Acaláns once lived here until driven out by their neighbors of Tabasco and Champotón; and their descendants resettled on the spot in the middle of the sixteenth century. A few mounds, one fairly large, were found on the shore of the estuary, while there is a slightly larger group about 4 km inland. The two groups are connected by a paved road, which crosses the mangrove swamp lying between them, and it is difficult to determine which was the pre-Spanish Acalán town. The region is of interest, as it represents the northernmost extension of the Maya Chontal at the time of the Conquest. It is now Hispanicized, but a possibility exists that a few Chontal-speaking families were still living not far from Tixel down to a generation ago.

FRANCE V. SCHOLES,
R. S. CHAMBERLAIN, AND R. L. ROYS
History of Yucatán

YB 39:277–280, 1940

In September 1939 the headquarters of the History of Yucatán project were transferred from Cambridge to Washington, D. C., where offices were provided for Mr. Scholes, Dr. Chamberlain, and Miss Adams in the Administration Building of Carnegie Institution. Mr. Roys has continued to reside in Vancouver but he plans to move to Seattle about September 1, 1940.

As stated in earlier annual reports, the lack of published documentary sources, as well as detailed monographic studies, on the colonial history of Yucatán has made it necessary to devote a long period of time to preliminary archival investigations. The study of Latin American history as a whole is characterized by these

same limiting factors, although the printed materials, both documents and monographs, are more extensive for other areas than for Yucatán. It is this state of affairs that makes many phases of Latin American history virgin fields for research, and at the same time imposes definite conditions on the character of investigations. In other branches of history, such as that of the United States, England, or modern Europe, students have the advantage of a large accumulation of detailed monographs and special articles summarizing spade-work research and serving as basis for works of synthesis. The Latin American field has lagged behind the others in this respect, with the result, that there are few major topics on which sound generalization is possible except after prolonged research in the original, documentary sources. This is particularly true of the colonial history of Yucatán, for which the available published sources that have merit consist of a few volumes of early chronicles and documents.

Publications by members of the History of Yucatán Project up to the present time have consisted in reproduction of documents and short papers on special topics. The immediate future calls for the publication of four or five monographs on special problems or limited chronological periods. These publications, completed and in preparation, will lay the foundations for the writing of the general history of Yucatán which is the chief aim of the project.

During the past year progress has been made in the preparation of the monographic publications. Mr. Scholes has pushed forward his investigations on the life and times of Bishop Landa. Miss Adams has extracted a mass of documentary material, consisting of royal decrees, lawsuits, petitions, and administrative orders on the *encomienda* system, forced labor, village government, and other phases of Indian administration in Yucatán. Materials of special interest for the research of Dr. Morley and Mr. Roys have been made available to them. Miss Adams and Mr. Scholes collaborated with Mr. Roys in the preparation of the paper on the early history of Cozumel, published during the year as *Contributions to American Anthropology and History*, no. 30. The monograph on the cacicazgo of Acalán-Tixchel, on which Mr. Scholes, Mr. Roys, and Dr. Chamberlain are collaborating, will be completed within a few months.

Dr. Chamberlain has been engaged in the preparation of the final draft of his study of the conquest of Yucatán. It was his original intention to approach this subject as a principal phase of the career of the Adelantado Francisco de Montejo, who also played an important role in the early history of Honduras and for a time was governor of Chiapas. The method thus envisaged was biographical and required that the history of Yucatán and Honduras should be wo-

ven about the figure of Montejo. As the preparation of his manuscript advanced he became convinced that such a method was not only illogical but lacking in unity. In view of the detailed treatment required, a narrative of events in Yucatán and Honduras drawn up on a biographical basis tended on the one hand to submerge Montejo as an individual and, the other, to distort the history of the two provinces. This would be unfortunate, since no exhaustive biographical study of Montejo, one of the outstanding lesser conquistadores of Spanish America, has yet appeared and little has been written concerning the history of Honduras during his years in authority there. In view of these considerations, Dr. Chamberlain has decided to divide his study into two separate monographs, one on the conquest of Yucatán and the closely associated province of Tabasco, and the other on the history of Honduras through the establishment of the Audiencia de los Confines. Each will be a unit in itself. At a later date he proposes to publish a less detailed study of Montejo as one of the founders of the Spanish empire in the New World. Preparation of the manuscript on the conquest of Yucatán now in its final stages. Dr. Chamberlain also published during the past year a short paper on the lineage of Montejo. Much of the past year has been occupied by Mr. Roys in seeing through the press *The Titles of Ebtún*; "Report and census of the Indians of Cozumel, 1570"; and "Personal names of the Maya of Yucatán."

The annotation of the Xiu family papers has been reviewed and completed; and for the introduction to these documents Mr. Roys has made a study of Indian nobility during the colonial period [Chapters 9.3, 9.7, and 9.15].

When the Spaniards arrived in Yucatán, they found a hereditary ruling class of long standing; but instead of attempting to destroy it, they appear to have seen in this Indian aristocracy a parallel to certain features of their own feudal system, which they preserved and encouraged. The Xiu probanzas, or proofs of nobility, constitute the chief evidence of the manner in which this institution was maintained in Yucatán but occasional references to it occur elsewhere. Mr. Scholes has also furnished copies of many documents from the National Archive of Mexico, which have aided greatly in understanding the situation in Yucatán.

In both Yucatán and Mexico the Spaniards called the higher nobility caciques and some times natural lords; lesser nobles were designated as hidalgos in Yucatán and principales in Mexico. As early as 1512 special treatment was prescribed by Spanish law for Indian chiefs in the West Indies; and later Philip II and his successors issued cédulas maintaining the rank privileges of caciques generally.

In colonial Yucatán the hereditary caciques were usually descendants of the pre-Spanish *batab*, or local head of a town; but some, like the *Xiu*, who were also called natural lords, were descended from the *halach uinic*, or territorial ruler. The cacique had the title of *Don* and was exempt from tribute and forced labor. His town was obliged to support him, rebuild and repair his home when necessary, and furnish him with domestic service. His precise functions are somewhat uncertain, as there was also an Indian governor in the town. We are told that the hereditary cacique had charge of and governed his town and was obeyed by the governor, but the functions prescribed in the latter commission are so numerous that it is difficult to determine what was left to the cacique. The Laws of the Indies confuse the two offices.

The cacique, however, had a place in the town corporation, where he doubtless exercised much influence. In Yucatán the *Xiu* caciques captured and returned fugitive Indians to their communities; they were also sometimes sent to other towns and appointed governor in place of an incumbent who was neglectful of his duties. In Mexico *Don Francisco Montezuma* was empowered by the Viceroy to protect his people from abuse by Spanish and Mexican shepherds. We find other caciques taking over the governor's duties during disputed elections, and successfully appealing in behalf of their towns for relief from illegal taxation, too frequent official visits of inspection, and interference by the clergy in local elections. From such activities as we find recorded, the cacique appears to have been more concerned with emergencies than with the usual procedure of municipal government.

Hereditary caciques apparently enjoyed more prestige and power in Mexico than in Yucatán, possibly owing to their superior economic position. We have little evidence of wealthy caciques in Yucatán, but in Mexico we find them owning extensive tracts of land, large herds of cattle, and various industries.

In Mexico the distinction between the caciques and lesser nobility continued to be observed down to the end of the colonial period; but in Yucatán after the middle of the eighteenth century they were all called *hidalgos*. They retained their exemption from tribute and forced labor, but the title of cacique had been appropriated by the town governor, although his office was only temporary. With the end of the Spanish regime in 1821, Indian nobility lost its legal standing, but some of the baptismal records of Yucatán continued to designate certain infants as *hidalgos* down to the middle of the nineteenth century.

By preserving and conciliating the Indian nobility the Spanish administration appears to have awarded its own interests as well as those of the class so favored. The conquerors were few in number com-

pared with the native population, and such a policy, in spite of some defection on the part of individuals, tended to keep the natural leaders of the Indians loyal, or at least acquiescent, to the Spanish regime. In Yucatán, the subject of this study, we believe that it aided greatly in controlling the natives and lessened the chances of insurrection. In any case the institution of native nobility in Yucatán and New Spain assumed an importance in the life of the Indian communities which has been very little realized by historians.

9.19.

FRANCE V. SCHOLES

Post-Columbian History

YB 40:309–310, 1941

Continued study of the documentary sources for the colonial history of Yucatán constituted the major activities of Mr. Scholes and Miss Adams during the past year. Most of these documents consist of series from Spanish and Mexican archives, of which photographs or typewritten copies had been made in former years. It may be recorded, however, that despite unsettled conditions in Europe, film copies of extensive series in the *Archivo General de Indias* in Seville have been received during recent months.

Most of the source materials studied during the year consisted of lawsuits, administrative reports, private petitions, and official correspondence which illustrate the following problems: 1. The preconquest political geography of Yucatán; 2. The government of Indian pueblos subsequent to the conquest; 3. The early history of the *encomienda* in the peninsula; and 4. The schedules of tribute payments. Notes and extracts based on the sources, together with similar data previously accumulated, have been carefully classified pueblo by pueblo, and this elaborate note file is producing dividends in the form of clues or answers to many hitherto unsolved questions in the early history of Yucatán.

For example, the tribute roll of 1549, the most important source of information for the beginnings of the *encomienda* in Yucatán, lists many pueblos which have been difficult to identify and locate. The accumulated pueblo by pueblo data have made possible positive identification of most of the doubtful entries. In the same way several questions concerning the pre-

conquest cacicazgos and their respective boundaries have been solved. Finally, the documents are yielding more and more information concerning the details of pueblo government and the functions of pueblo officials subsequent to the conquest.

These problems have great importance for the studies of Mr. Roys and Dr. Chamberlain, as well as for the investigations of Mr. Scholes and Miss Adams. In the summer of 1940, Mr. Roys came to Washington for a series of conferences with his colleagues, during which the documentary evidence relating to questions of common interest was thoroughly reviewed. These conferences proved extremely valuable, and satisfactory answers were worked out for many moot points. It was clear, however, that first-hand information, obtainable only in the field, will be required to supplement the documentary data on several questions relating to preconquest political geography, or to make possible more accurate interpretation of such data. For this reason Mr. Roys and Mr. Scholes plan to spend a few weeks in Yucatán during the winter of 1941–42, in order to visit certain key areas, especially in the eastern part of the peninsula.

During the past year, Mr. Scholes has also completed a series of articles on the history of New Mexico in the seventeenth century, which have been published serially in the *New Mexico Historical Review*. These articles are based on source material obtained from foreign archives prior to the time he joined the staff of the Division. During 1941–42 Mr. Scholes will serve as visiting lecturer at the University of New Mexico. The program of research on the history of Yucatán will be carried on as usual, however, except that headquarters for the year will be established in the Southwest instead of in Washington.

Dr. Chamberlain has devoted most of the year to further revision of his manuscript on Montejo and the Spanish conquest of Yucatán, preparatory to publication of this important study, which will be the first in a series of volumes on the colonial history of the province. Mr. Roys has also actively collaborated with Dr. Chamberlain by preparing materials for a survey of Maya institutions and culture on the eve of the conquest, to be incorporated in Dr. Chamberlain's volume.

In Mexico City, Sr. Rubio Mañé has continued his survey of a section of the National Archives known as the *Papeles de Bienes Nacionales*. The great volume of documents in this series, which consists of ecclesiastical archives, has made the survey a longer task than was expected, but when the work is completed, Carnegie Institution will have made a valuable contribution to the work being carried on by the archive, which contains the greatest collection of colonial materials in North America.

9.20.

FRANCE V. SCHOLES, AND R. L. ROYS
History of the Maya Area

YB 41:275–278, 1942

Mr. Scholes spent most of the past year in Albuquerque, New Mexico, with headquarters at the University of New Mexico. For several years the university, which is strategically located in an area which has strong historical and cultural ties with Hispanic America, has stressed Americanist studies, and in 1941 a School of Inter-American Affairs was created to give direction to this program. Mr. Scholes, who had been head of the History Department of the University prior to joining the Division of Historical Research of the Carnegie Institution, was invited to serve as Lecturer in History for the academic year 1941–42 and to give a graduate course in the bibliography, methods, and problems of Spanish colonial history. Instruction in this course was given once a week for two hours throughout the year. Mr. Scholes also served at times as an adviser on problems relating to the general program of inter-American studies.

Research under the History of Yucatán Project was carried on as usual by Mr. Scholes and Miss Adams in offices at the university library. Progress was made in exploiting a large accumulation of archival materials from Spain, Mexico, and Yucatán, especially with reference, to studies being made in collaboration with Mr. Roys, and it is expected that these will be completed, by the end of 1943. It was Mr. Scholes' intention to visit Yucatán between the first and second semesters of the university term, but this plan was abandoned early in December.

In October Dr. Chamberlain was granted leave of absence from the Carnegie Institution to permit him to accept an appointment as Senior Cultural Assistant at the United States Legation in Guatemala City. Consequently his work on the conquest of Yucatán has been temporarily suspended.

The employment of Sr. J. Ignacio Rubio Mañé terminated December 31, 1941. Since 1935 he had been engaged in archival investigations in Mérida and Mexico City. As a result of his researches a vast amount of new documentary material relating to the history of the Yucatán peninsula has been made available. In accordance with an agreement made in 1939 by Mr. Scholes and the officials of the Mexican National Archive, Sr. Rubio Mañé spent the past two years on an inventory of the *Papeles de Bienes Nacionales* section of the Archive, which contains almost 2,000 bundles of ecclesiastical papers of the colonial period, notably

materials for the archdiocese of Mexico City. The inventory, which Sr. Rubio Mañé completed in December, is now available for use by all students of the colonial history of Mexico. Carnegie Institution wishes to take this opportunity to express its appreciation to the Director and other officials of the Mexican Archive for courtesies extended to Sr. Rubio Mañé and other members of the Division staff during the past few years, and to record its thanks to Sr. Rubio Mañé for his loyal service in connection with the History of Yucatán Project.

Much of the past year has been spent by Mr. Roys in the completion of a survey of the institutions and culture of the Yucatecan Maya during the period immediately preceding the Spanish conquest. New documentary sources discovered and made available by Mr. Scholes and a closer study of other Maya documents have been found to supplement and cast increasing new light on the published reports of the earlier Spanish writers.

Evidence is accumulating regarding a ruling class in Yucatán, apparently composed of families claiming to be descended from former Mexican invaders. This group not only controlled the political organization, but also monopolized the priesthood. Since a knowledge of hieroglyphic writing was confined to the priests and some other members of the nobility, we have an anomalous situation, in which the principal key to Maya science was in the hands of a class of allegedly foreign origin.

In contrast with conditions reported as widely prevalent in the highlands of Mexico, in at least four, and probably more, of the native-states of Yucatán we find what appears to have been a genuine territorial government, in which the head of the principal town not only confirmed and controlled the heads of the other towns of his area, but also frequently put his own appointees into such positions. Although the local head acted in a judicial capacity in his town, he was obliged to refer certain serious cases to the territorial ruler. Finally, the latter kept track of the boundaries of his state, inspecting them personally from time to time to prevent trespass on the part of aggressive neighbors. Other states, however, had no single ruler, but consisted of allied towns or groups of towns, in which the local head was likely to belong to the most prominent lineage group of the region.

A third point of interest emphasized by the more recently discovered source material is the extensive trade which existed between Tabasco, Yucatán, and Hibueras-Honduras, the last being the northern coast of what are now Guatemala and Honduras. Although the languages of the Maya stock largely spoken in all three areas were very similar, scattered Mexican speaking colonies were also found in Tabasco and

Honduras which were especially active in trade. Notwithstanding such differences in language and culture as existed, commercial relations appear to have been so close that the three countries could well be considered a single economic area. Campeche people had trading posts on the Ulúa River in Honduras, and the Chontal-speaking Acaláns of southwestern Yucatán occupied an entire quarter at Nito, a famous commercial center near the mouth of the Río Dulce. Generally speaking, the Yucatecan Maya exported cotton cloth, salt, honey, and slaves to their neighbors on either side and received in return metal objects, cacao, feathers, precious stones, and other luxuries. That these commercial relations created a certain community of interest is shown by the evidence of military alliances, which appear to have existed between some of the Yucatecan towns and those near the coasts of Tabasco and Honduras.

Many of the articles imported into Yucatán by way of Tabasco and Hibueras came originally from the inland neighbors of the last two. Early in 1942 Mr. Roys went to Guatemala, where a study was made of the region in which Nito was said to have been situated, and of what appear to have been two of the most important natural trade routes into the interior. One was the Motagua River, on which merchandise could be transported by canoe to the foot of the rapids not far below Gualan. The other was the water route formed by the Río Dulce, Lake Izabal, and the Río Polochic. Passenger launches now operate on the latter from the sea to Panzos, beyond which the river is navigable for canoes as far as La Tinta. Cacao plantations were reported on both the Motagua and Polochic by the first Spanish explorers; and the maize land in the valley of the Polochic is still considered to be especially good. The navigable part of the Motagua furnished access to the Chortí country, and on the Polochic canoe traffic reached the Pokonchí area and probably also the Kekchí. Regarding the Chortí, it is of interest to note that recent ethnological investigations indicate that their culture resembles that of Yucatán more than it does that of the western highlands of Guatemala [Chapter 9.19].

Mr. Roys, in company with J.E.S. Thompson, visited a number of archaeological sites along the Pacific slope of Guatemala formerly occupied by Mexican speaking immigrants. Many of these people were still living in various parts of the region at the time of the Spanish conquest, and a colony of them existed in central Guatemala. The language, known as Pipil, is still spoken in Salvador, but seems to have disappeared in Guatemala within recent years. Their sculpture has significance for the history of Yucatán because of its resemblance to that of the Mexican period in the latter country. In both cases, as Mr. Thompson has recently

shown, various features of the culture reflected by the sculpture appear to have been brought from a common source in southern Veracruz.

Such analogies seem less noticeable in the western highlands of Guatemala, but here, as in Yucatán, native historical legends indicate that the ruling class believed itself to be descended from people who had come from the Gulf Coast of Mexico. A considerable number of archaeological sites were visited in this region, particular attention being given to those which were occupied at the time of the conquest, among them Utatlán, Chuitinamit on Lake Atitlán, Iximché, Zaculeu, and Rabinal. The ruins of Rabinal are the best preserved, and its remains are imposing. Situated on a high, barren ridge above a large, fertile valley and well protected from attack by its location, the site consists of eight ceremonial plazas, two containing excellently preserved ballcourts. One of the latter is set into the upper floor of a plaza which was laid out on two different levels. In each complex the most prominent buildings are a central temple and a long, narrow house at one end. Both are set on substructures and have walls of rough, flat stones laid in mud mortar but covered with a thick coat of lime plaster. The dimensions and general appearance of these buildings suggest that they had borne flat, beam-supported roofs. Although a number of house sites were observed on the slopes adjoining the plazas, the location is such that it seems unlikely that a large population resided permanently at the site.

At Salama, a short distance east of Rabinal, there was formerly a group of Mexican-speaking Indians, who have been completely absorbed by the local Ladin population. Two days were spent in questioning a number of the older people, who remembered this group, and a few of their Hispanicized descendants. It is of interest to note that they were apparently little influenced by their Rabinal-Quiché neighbors. Although the latter, especially those of the nearby town of San Miguel Chicaj, have always visited the Salama market regularly, it is generally agreed that the local Indians had little to do with them.

Returning to the United States through Mexico, Mr. Roys visited Teotihuacán and Tula, the latter being of especial interest to the student of Yucatán because of the remarkable resemblance of the sculptures recently uncovered there to those of the Mexican period at Chichén Itzá.

FRANCE V. SCHOLES, AND
RALPH L. ROYS

History of the Maya Area

YB 42:181-183, 1943

During the past year Mr. Scholes has devoted a large part of his time to preparation of chapters for the volume on the history of the cacicazgo of Acalán-Tixchel to the early seventeenth century. In the spring of 1943 Mr. Roys, who is collaborating in this work, spent four weeks in Albuquerque with Mr. Scholes, during which time various problems connected with preparation of the manuscript were ironed out. The volume will be ready for the press not later than the autumn of 1943.

From time to time during the past year documentary materials relating to other topics have been studied and extracted. Papers based on these sources will eventually be prepared for publication, but certain points should be noted at this time because of their obvious interest for specialists in Maya studies.

One series of documents contains data concerning native ruling families in the Chancénote area, or cacicazgo of Tazees. We learn that a certain Ahau Chan was lord of eight towns in this region prior to the conquest and for some years after the arrival of the Spaniards. He was succeeded by his son, Don Juan Chan, and the latter, in turn, by Don Juan Chan the Younger who was cacique and governor of Chancénote for almost 30 years during the latter part of the sixteenth century and the early years of the seventeenth. Chan the Younger married Doña Isabel Tzeh, daughter of Don Fernando Tzeh, who was natural lord of the other towns in the Chancénote area and "descended from the ancient lords of Mayapán." Thus we have record of other Maya families which, like the Xiu, the Pech, and the ruling house of Acalán-Tixchel, were able to retain a measure of power after the conquest, and we learn of another line of rulers which traced its ancestry back to chieftains resident in Mayapán prior to the disruption of the confederacy and the abandonment of the city. The name *Tzeh* suggests that the cacicazgo of Tazees derived its name from this family.

During his term of office as governor of Chancénote, Don Juan Chan the Younger received various commissions from the governors of Yucatán and performed numerous services which contributed to the advancement of the missionary program. He took an active part in the resettlement of fugitive and heathen Indians in the eastern and coastal areas of the province, and on one occasion collaborated with Dr. Pedro

Sánchez de Aguilar, cura of Chancénote, in the extirpation of idolatry. The Chan papers are supplemented by the probanzas, or proofs of services, of Sánchez de Aguilar, which also mention the idolatry incident. Although the two sets of papers do not contain, much detail concerning this episode, it is recorded in one place that during the affair, which occurred about 1604, Sánchez de Aguilar destroyed more than 20 idols and "three books of heathenism and idolatry written on the bark of trees with the figures of devils which they worshipped." So it appears that Sánchez de Aguilar must share with Landa and others responsibility for the destruction of many of the ancient hieroglyphic writings of the Maya. In later years Sánchez de Aguilar wrote the well known treatise *Informe contra idolorum cultores del obispado de Yucatán*, thus emulating in another respect the example of Bishop Landa, author of the famous *Relación de las cosas de Yucatán*.

Another series of documents describes the serious disorders which occurred in the pueblo of Sahcabchen, southeast of Champotón, and in adjacent areas in the 1660s and 1670s. Although the major causes of unrest were abuses committed by provincial authorities and raids by English ships along the Gulf Coast, we are also told that one source of trouble was the activity of certain Indians, including a native priest, who went about preaching that according to prophecies the time had come for the Indians to abandon their settlements and take refuge in the bush, and forest regions of the interior. Interpretation of these data will require considerable study, for the information is by no means explicit. The testimony may refer to one of the year prophecies, but it seems more likely that a k'atun prophecy, such as we find described in the books of Chilam Balam, is indicated. These documents and the idolatry episode mentioned, in the preceding paragraph serve to illustrate the survival of Maya religion and the influence of the native priesthood.

From the Sahcabchen papers and the documents which comprise part of the source for the Acalán-Tixchel volume we are able to glean interesting data concerning settlements of fugitive and apostate Indians in the central and southern part of the peninsula in the seventeenth century. Some of these settlements were located in the Matamoros-Cilvituk-Chan Laguna region, and chapter 9 of the Acalán-Tixchel volume will deal with missionary enterprise in this area from 1604 to 1615.

Perhaps most interesting, in view of the growing interest in the archaeology of southern and southwestern Campeche, are references to the site called Bolonpetén. Maler was the first person in modern times to mention this place. In his *Explorations in the Department of Petén, Guatemala, and Adjacent Regions* (1910:146), he described his journey through central Yucatán, and

in connection with his account of the Cilvituk ruins he wrote:

Incidentally . . . about the middle of the nineteenth century, many free Maya families still dwelt in the precincts of Chanlaguna and Cilvituk. Their principal settlement is said to have been at Bolonpetén, some two leagues west of Chanlaguna. This is a swampy region containing islands, hence the name, "Nine Islands." Many pottery sherds are said still to lie around there, but the people themselves have totally disappeared.

Andrews (1943:37) gives additional information concerning this swampy area. He states that it is called *Isla Pac*, which "means in Spanish-Maya 'island with walls,' or 'island with ruins.'" Continuing the discussion, he notes that the ruins at Isla Cilvituk and Las Ruinas north of Isla Pac are "among the last products of indigenous architecture," and states the belief that the ruins in Isla Pac, or Bolonpetén, if found, "might well bridge the gap between our knowledge of late pre-Spanish archaeology and early historical information. Or they might prove that the two overlap."

From the documentary sources we learn certain facts concerning this place. A document of 1605 refers to it as an old site (*asiento antiguo*). The exact meaning of this phrase is not clear, but the context implies that the place was not occupied in 1605. The Sahcabchen papers describe it as a place "surrounded by nine small islands (*islotes*)," from which it was possible to go by canoe to Popolá, located on or near the lower course of the Mamantel River. It was inhabited at this time (1670) and its cacique was one of the leaders of the malcontent Indians of the interior. We have no positive record that the place was occupied at the time of the conquest, but there is some evidence that when the Spaniards arrived some of the Cehache settlements may have extended as far north as the Cilvituk region. Data on this point will be presented in the Acalán-Tixchel volume.

Dr. Chamberlain, who is on leave of absence, continued to serve as Senior Cultural Assistant of the United States Embassy in Guatemala City.

9.22.

FRANCE V. SCHOLES, RALPH L. ROYS,
AND ELEANOR B. ADAMS*History of the Maya Area*

YB 43:178–184, 1944

During the past year Mr. Scholes and Mr. Roys have devoted a large part of their time to the volume on Acalán-Tixchel. Mr. Roys was also occupied with details of proofreading and indexing his recently issued work entitled *The Indian Background of Colonial Yucatán* (1943; 1972).

In the course of the year various series of documents relating to the colonial history of Yucatán have been extracted in preparation for other studies in progress. Two groups of these papers deserve notice at this time.

Of special interest to the historian and the ethnologist is the probanza of services of Padre Antonio de Arroyo, a native of Yucatán, who served for seven years (ca. 1586–93) as cura and vicar of Chancénote, and later (ca. 1593–96) in a similar capacity at Peto. From 1597 to 1603 he officiated as a cura in the cathedral of Mérida, and in 1598 was appointed visitor general for ecclesiastical affairs in Tabasco by the bishop, Fray Juan Izquierdo. In 1603 he also had charge of the parishes of Santiago and Santa Ana in Mérida.¹

In 1592, while serving at Chancénote, Arroyo was authorized by the episcopal authorities (Bishop Izquierdo and his vicar general, Br. Pablo de León) to make an investigation of idolatry in the pueblos of the Chancénote area, where it was reported that many Christian Indians still practiced the “rites, ceremonies, and sacrifices of idolatry as in ancient times.” He was instructed to find out who these Indians were and the number of idols they possessed, and he was particularly charged to discover who served as *ah kins*, or native priests, “and the artisans who make the idols . . . and the [persons] who serve as *chaques* [*chacs*].” If possible, he was also to learn where the Indians kept their “books of idolatry” and where the idolatrous ceremonies were held. It should be noted, however, that his instructions expressly stated that he should proceed “with piety and mercy,” imposing no pecuniary penalties and assuring guilty parties that if they would be good Christians in future a just and mild penance would be granted. In the case of the native priests and the artisans who made the idols, the bishop reserved to himself the right to pronounce sentence.

The probanza indicates that numerous procesos were formulated as the result of these orders, and there is evidence that many of them were left on file, prob-

ably in the episcopal archive, a decade later. Unfortunately copies of these procesos were not incorporated in the probanza proceedings, and we assume that they are now lost. But the probanza records certain details which illustrate Arroyo’s activities and the prevalence of idolatry in certain towns of the Chancénote district.

In Nabalam, where an investigation was made with the aid of Don Marcos Copul, cacique and natural lord of the pueblo, a considerable number of “*hechiceros, sortilegos y idolatras*” were punished. In the pueblo of Tixholop the cacique, Juan Tzama, was found guilty of idolatry, and we are told that the village of Tixmucul was “almost lost” because of the widespread practice of native religion there. Two native priests of Tixmucul are mentioned by name (Pedro Cocom and Juan Hun), and the testimony also states that Arroyo went in person to the milpas of the town; where he removed many clay idols, “which [the Indians] worshiped as gods.”

In 1595 Arroyo made a similar investigation in the pueblos of the Peto district. Again we have references to the large number of procesos that were formulated and sent to Mérida, but, as in the case of the proceedings at Nabalam, Tixholop, and Tixmucul, the actual documents are missing. It would appear, however, that in the Peto area idolatry was even more widespread than in the northeast.

Don Melchor Xiu, governor and cacique of Calamud (Calotmul), who later gave testimony as a witness for Arroyo, stated that in his own pueblo “almost all the citizens [*vecinos*] were public and secret idolaters.” Here the priest punished many “*hechiceros*,” both men and women, and removed more than 600 idols. The probanza also tells about a certain Juan Puc, “was bishop . . . who, as chief of the said idolatry, was respected and obeyed.” This “bishop” made use of a miter, described as being made of a manta painted yellow, a cope (*copa*), hyssop, “and other trappings of a pontiff and bishop,” and he also had certain “books of idolatry.” He was assisted by four other native priests, Juan Huh, Juan Na, Diego Chan, and Juan Mo, “who in the ministry of idolatry had divided the said pueblo of Calamud into barrios (*parcialidades*) and *cofradías*.” From all these leaders Arroyo took away numerous “idols, trappings, and offerings of copal incense, *cuzcas*, *piedras*, cacao, and clothing which had been offered to the idols.”

Don Antonio Pot, cacique and governor of Dzitnop, and Don Gaspar Chan, cacique and governor of Chunhuhub, were also guilty of idolatry and were publicly punished along with many other Indians of their towns. Many other natives confessed in secret and handed over their idols.

It is evident that although a large number of Indians in the Chancénote and Peto areas were publicly

chastised, the punishments were not severe. The bishop's instructions, as noted above, forbade the use of stern measures, and the testimony recorded in the *probanza* tells how Arroyo, by persuasion and mildness, induced the Indians to abandon their idolatrous practices. This is in sharp contrast with the record of Landa's investigation of 1562. It is true, of course, that we have no evidence of human sacrifice in these later documents, so that there was not the same need for drastic measures. Nevertheless, it seems clear that the bishop and his agent, Arroyo, consciously adopted a policy of persuasion and mild punishments, and this may indicate a new tactic in dealing with Indians who had reverted to their old religion and ceremonial practices.

The actual *procesos* in these idolatry cases of 1592 and recorded a considerable amount of data concerning Maya religion and the manner in which it was carried on in post-conquest times, but the documents are apparently irretrievably lost. Above all, it is unfortunate that the "books of idolatry written in figures and characters" that were taken from the Indians, and were still preserved in Mérida in 1603 are now missing.

During the year Miss Adams has been making a study of numerous documents relating to French corsairs in the Yucatán area. The activities of these corsairs on the coasts of Yucatán and Campeche during the sixteenth century form an integral part of the whole history of the operations of French and English privateers and pirates in the Caribbean in that period. Although the commercial importance of this province and its principal port, San Francisco de Campeche, was comparatively small, their location, in close proximity to Cuba, Florida, and the New Spain port of San Juan de Ulúa, made the possibility of any serious foreign encroachments there a potentially great danger to Spanish supremacy in the whole region. Moreover, the New Spain fleet passed close to these coasts, and if the Mainland fleet was to touch at Havana, it also had to pass near the Yucatán peninsula. The presence of corsairs along the Yucatecan shore was also a menace to all local coastal trade from New Spain to the Río de la Hacha, and to the trade carried on with the islands.

Although French adventurers, especially Norman sailors, were the first to challenge Castilian monopoly in the Caribbean, the story of the most important period of their piratical activities, which began in the 1530s and continued into the 1590s, has been told only in part. During his researches in the Archive of the Indies at Seville and the Archivo General de la Nación in Mexico City, Dr. Scholes photographed a number of documents dealing with French attacks on Yucatán and Campeche which contain a large amount of new material concerning French depredations there and also supply hitherto unknown details illustrating the cooperation between French and English corsairs in

their voyages to the Guinea coast and thence to the Spanish Main, during which they engaged both in illicit trade and in outright piracy. The most extensive of these documents make an interesting addition to the known accounts of Francis Drake's voyage to the Indies of 1571, when he apparently joined with the French for a time in harassing the Spaniards at the Chagres River. These papers, which consist of the trials by the Tribunal of the Holy Office in Mexico City of a number of French corsairs captured at Cozumel in 1571, supplement the accounts given in Wright (1932) of the operations of the English and French on the coast of Tierra Firme in that year.

The first time the French appeared in Yucatán was in the port of Campeche in 1559 after attacks on Santa Marta, Cartagena, and Puerto de Caballos. Although the details are not clear, it seems that they were driven back to Yucatán by a storm and voluntarily gave themselves up, stating that they had received news of the peace between France and Spain. Some of them were sent to the viceroy in Mexico City, and we do not know what was done about this group. The chief account we have of this incident is in the Inquisition trial of 12 who remained in Yucatán. The Tribunal in Mexico City had not then been created, and proceedings were instituted by Fray Francisco Navarro, guardian of the Mérida convent and commissary general of Yucatán, as ecclesiastical judge ordinary in accordance with the papal bulls which allowed the Franciscan prelates to exercise such jurisdiction where there was no bishop. As in all such instances, the main interest of the ecclesiastical authorities was in the heretical beliefs of the culprits, and their crimes of robbery and arson were investigated merely as proof of their pernicious lack of orthodoxy. Because of this attitude, the records of this trial and of those of other Frenchmen tried in later years before the Tribunal in Mexico City are tantalizingly difficult to use for our purposes. No attempt was made to compile a complete account of their piracies. The examinations of culprits and witnesses were all based on the desire to find out whether the accused belonged to the followers of Martin Luther (to the Spaniard of that time the term "Lutheran" included all Protestants), whether they had shown in word or deed any disrespect for the teachings of the Holy Mother Church, and whether they had committed sacrileges.

In Yucatán in the early months of 1560 fear and hatred of the foreign heretics had not yet reached the heights to which they were to mount within a very short time. Local citizens were appointed to defend the Frenchmen and seem to have taken fairly seriously their obligation to present a good case for their charges, aided in this by prudent professions of penitence for their errors on the part of the accused. The sentence

imposed public penance, varying according to the degree of guilt, and only one man was condemned to corporal punishment. In addition to public penance, he was sentenced to 100 lashes and one year of service in the Mérida cathedral. Whether any of these men were able eventually to return to France is a question.

The names of some appear on a list in the Cathedral at Mexico City, where they are described as heretical pirates reconciled in the Year 1560. In August, 1561 the Spaniards were greatly alarmed by an attack on Campeche by three ships from Dieppe. The inhabitants of the villa fled to the bush, and some of the French went ashore, took everything of value they could lay their hands on, set fire to the town, and carried off five women. About 15 citizens and an equal number of soldiers from Florida, who had arrived opportunely the day before, went out in pursuit of the French and were able to kill some and take five prisoners. The rest fled to their ships in a small boat, leaving their booty behind. The prisoners were hanged without delay, and warnings were dispatched to Veracruz.

Although no other major incidents occurred on the coasts of the peninsula until 1571, from 1561 on the Spanish residents were greatly concerned about the danger from such attacks. Throughout the rest of the century representations were made to the Crown at frequent intervals, urging the need of fortifying the more vulnerable points, especially the villa of Campeche, and of providing arms and munitions for defense. It was not until the early seventeenth century, however, that the fortifications at Campeche were begun, although various defense measures of lesser importance were adopted from time to time. Such information as we have for the period 1562–70 comes from widely scattered sources; these accounts are usually brief and unsatisfactory and often give no dates or exact detail.

In 1571, however, the citizens of Yucatán again had the satisfaction of capturing some of the Norman heretics who had kept them so uneasy about their vulnerable coast line. French corsairs appeared at Cozumel during Holy Week and seized a vessel which was on its way to Honduras with a cargo of mantas, wax, and honey.

A few days later some of the French landed at Sisal and went inland as far as Hunacama. A force sent from Mérida when the alarm was given was too late to overtake them, and shortly thereafter Governor Céspedes sent three boats to search for them. During the following weeks the corsairs were reported from various places, and in late May they turned up at Conil, where they seized a vessel from Trujillo, Honduras, with a cargo of wine, oil, and other merchandise. Some days later about 20 of the pirates, were surprised at Ecab by a force sent out from Valladolid. The French ships sailed away, and the men who had been

left behind fled along the coast to Pole. Meanwhile a second force was sent from Mérida to aid the one from Valladolid, but by the time they reached Pole the Frenchmen had crossed to Cozumel, where the Spaniards finally overpowered them. Nine or 10 were killed in the battle, and 10 were taken prisoner. Four of the latter were tried and hanged in Mérida by the civil authorities, but we have no record of the proceedings. The other six remained in Yucatán until they were sent to Mexico City in 1572 to the newly established Tribunal of the Holy Office. The mass of confusing testimony in the cases against these men touches on their exploits from the time they sailed from Honfleur until they were deserted by their companions at Ecab. Their confessions show that all were natives of Normandy and that some had taken part in the Civil Wars in France on the Huguenot side. So much prejudice and vengeful feeling enters into the testimony against them, and their own admissions are so colored by their efforts to make a favorable enough impression upon the Inquisitor to save their skins if nothing more, that it is difficult, to determine just what can be relied upon as fact. The study of these papers is still in its preliminary stages, but after comparing them with the documents published by Miss Wright and her valuable introduction to them, it is already clear that these Frenchmen belonged to the same group who were harassing the coast of Tierra Firme independently and with Drake in 1571, for many names and events correspond.

French corsairs continued to turn up in the vicinity of Yucatán until the early 1590s, for besides preying on local shipping, they found the stretches of sparsely inhabited coast useful when it was necessary for them to put in for repairs or to obtain food supplies from the Indians. Most of the information we have about their activities after 1571 is of the same sketchy and unsatisfactory nature as that for 1562–70, but there is no doubt that the necessity for being constantly on the alert against them was a continual problem for the residents of Yucatán. By the end of the century the French incursions in the Yucatán area had practically ceased, and the great period of the English and Dutch buccaneers was dawning.

In addition to his study of the pre-Spanish history of the Acalán, Mr. Roys has investigated the implications of this material for the history of northern Yucatán and Tabasco. The Acalán ruling class was a mobile group, presumably from Tabasco originally, and the bearers of a more or less modified Mexican culture. During the course of the narrative that has come down to us, they moved first from northeastern Yucatán to the Usumacinta River, and finally to the Candelaria basin in southwestern Campeche, where they carried on an extensive commerce reaching from the Gulf of Mexico to the Caribbean Sea.

On the basis of the native historical legends, the observations of the first Spaniards, and the result of modern archaeological investigations, a tentative effort has been made to trace the effects of an intrusive Mexican culture in the northeast and along the Caribbean coast of the Yucatán peninsula, as well as in Tabasco.

Though the influence of this culture is evident in all three regions, it appears to have been strongest in Tabasco, where, even within the Chontal area, a number of Nahuatl-speaking towns existed. In Acalán it lessened somewhat; and in northern Yucatán, although its effects are evident, it appears in a much more attenuated form, particularly during the period immediately preceding the Spanish conquest.

Acalán was closely associated with Tabasco, where the same Chontal language was predominant. Comparatively little information has come down to us concerning the latter area until very recently, but with the aid of a number of early Spanish documents brought to light by Dr. Scholes, it has been possible to draw a more intelligible picture of this rich and important country, as it was at the time of the Spanish conquest. In addition to our previous general knowledge of the visits of merchants from Mexico, we are informed of their warehouses in certain Chontal towns and of the retail distribution of goods from these depots to the consumer. More detailed information is now available concerning the activities of the Tabasco traders, who ranged from southern Veracruz to the Ulúa River in Honduras, and of the Yucatecan Maya towns in various parts of the peninsula, whose merchants had also established factories in the latter area. The historical importance of Tabasco has become increasingly apparent with the growing belief among archaeologists that the Mexican invaders who so strongly influenced a great part of the Maya area passed largely by way of this region.

It has long been known that nearly all the Chontal-speaking towns in Tabasco have been designated only by Mexican names ever since the conquest; but it is surprising that the documents give only Nahuatl personal names for the inhabitants of these towns. In the case of converts this often became a surname, and was preceded by a Christian name. In the Acalán records, however, the place names are all Chontal, but the personal names are a mixture of Chontal and Mexican, the latter often in a corrupted form. Some of these cast new light on a number of Yucatecan Maya names of doubtful origin. A tentative analysis of an early Tixchel list of tributaries will be presented, as an appendix to the forthcoming volume on Acalán-Tixchel.

As yet this list is the earliest extensive compilation of native names from the lowland Maya area that has come down to us. The ethnological and sociologi-

cal implications have been studied, and it offers certain puzzling features. Chief among these is the apparent evidence of a much stronger tendency toward matrilineal residence than we should expect in this region. Some possible explanations have been suggested, but these are not conclusive, and the attempt has been principally to formulate the problem involved.

NOTES

1. The probanza is in Archivo General de Indias, Mexico, legajo 294.

9.23.

FRANCE V. SCHOLES, RALPH L. ROYS,
AND ELEANOR B. ADAMS
History of the Maya Area

YB 44:177-183, 1945

During the past year additional manuscript sources have been examined and extracted in preparation for studies on the colonial history of Yucatán. A brief review of certain data of interest to workers in other branches of Maya research will be made at this time.

The survival of native religion in postconquest times, concerning which other materials have been summarized in previous reports, is further illustrated by documents relating to the visita of Yucatán made in 1583 by Dr. Diego García de Palacio of the Audiencia of Mexico. In a letter to the Crown dated at the Villa de Valladolid December 26, 1583 (AGI México, legajo 70), Palacio stated that the practice of idolatry was widespread throughout the entire Valladolid district. At Tzamá and Polé on the East Coast and also in the towns of San Miguel and Santa Maria on Cozumel Island, all the Indians "without exception" were said to be idolaters. At Tzamá there had been a "temple of idols" where the Indians gathered to celebrate "festivals, dances, and other ceremonies as in ancient times." We surmise that this place was simply the *popolna*, defined in the Motul dictionary as the "casa de comunidad," where certain dances were taught. In such case, the Indians no doubt had regular temples in the bush, as was true on Cozumel Island (Roys, Scholes, and Adams 1940:27). This "temple" at Tzama had now

been burned, presumably by order of Palacio, and all the more than 500 idols had been smashed and cast into the sea.

Palacio goes on to state that the common people guilty of idolatry had been given mild punishments, but the caciques, native priests, "and the *maestros* who made the statues (*estatuas*) and figures" had been arrested and would receive more severe punishment; "because in view of the boldness and excess with which they have lived in this sin, it is necessary, in order that henceforth mercy should not give them reason for greater obstinacy, as apparently has been the case up to the present time. The reference to *maestros* (masters, teachers, artisans) who made the idols is of some interest. The word *estatuas* usually seems to mean wooden idols, and Landa gives an account of the making of such figures. Palacio's letter and a supplementary report refer, however, only to clay idols, so in this case the *estatuas* were apparently of this kind.

The prevalence of idolatry on the east coast and Cozumel is not surprising, since the towns of this region were located at some distance from the nearest mission centers. Palacio's letter states, however, that in towns situated only one, two, or three leagues from the Villa de Valladolid similar conditions prevailed. On one journey outside the villa he had collected 1,160 idols, in addition to many others that were destroyed, and had punished more than 600 idolaters. He had also banished from this area certain "dogmatizers, priests, and *maestros*" of these idolaters.

A supplementary report (Valladolid, 12 diciembre, 1583; in AGI Mexico, leg. 70) describes some of these 1,166 "*quiçines*," or idols, that had been gathered up. Some were said to be as large as children 3, 4, and 5 years old. Others were "figures of men with emblems (*divisas*) of animals on their heads, and others with miters and tiaras and other headdresses of men and women according to ancient custom, which the said Indians were accustomed to wear . . . in their sacrifices, festivals and rites when they performed their idolatry."

Figures of men with "emblems of animals" on their heads are familiar in the Maya codices and on the monuments. Some of the animal headdresses have been thought to be carved wooden helmets. Clay figures of this kind were probably gods, including deified men. The "miters" suggest Mexican tradition, and figures with such characteristics may have represented deified lineage ancestors, old invaders (?). The significance of "tiaras" in the case of gods is not clear. Gem studded-bands seem to be found on both gods and warlike men at Chichén Itzá: on caryatids, "chacmools," and relief figures. The first Spaniards found gold headbands in chests in the temples of northern Yucatán and obtained others in Tabasco. We are in-

clined to associate them principally with deified heroes or lineage ancestors, but they may have a wider scope.

The report describing these idols also mentions figures of "*leones*, *tigres*," and dogs, and "temples (*cues*) of different plans and forms." The pumas and jaguars of architectural sculptures evidently represent the military orders, but here we presumably have actual gods. The "*leones*" may have represented the war god, *Cit-chac-coh* ("father-red-puma"). The Book of Chilam Balam of Chumayel mentions a *Chac-bolay-balam* (*chac-bolay* means "*tigre bermejo y bravo*") and a *Chac-bolay* also figures in the Tizimín manuscript. We find no mention of dog gods in the colonial literature, Maya or Spanish. Figures of dogs are familiar, however, in the codices, and in the Dresden 7a, a dog appears in a long row of deities. Dogs were also a favorite sacrifice, and Landa tells of offerings of clay dogs with bread on their backs. The figures mentioned in this 1583 report may have been something like votive offerings, if they were not idols of a dog god.

Despite the punitive measures imposed by Dr. Palacio, idolatry continued to exist in the Valladolid area and other parts of the province. A letter of Bishop Vázquez de Mercado dated May 2, 1606 (AGI México, leg. 72) records that "Indian idolaters were daily being discovered in various towns of this diocese." During a visitation made by the bishop in the Valladolid district "there were discovered and punished more than 80 Indians who, in gangs (*cuadrillas*), assembled in different pueblos to perform the said idolatries." Moreover, a benefited priest in that area had recently sent a report of 56 other idolaters whom he had found in the towns of his benefice. They had clay idols "*de mallsimas figuras . . . que a unos llamaban Dios Padre, a otros Dios Hijo y a otros Dios Espiritu Santo y Santa Maria y a otros muchos nombres de santos, y santas como a ellos les parece, teniendo los dichos sus sacerdotes que hacian las ceremonias y sahumerios cuando todos se juntaban a idolatrar.*"

This reference to clay idols called God the Father, God the Son, God the Holy Spirit, Holy Mary, and other names of saints is reminiscent of a report by Francisco Hernández in 1545 (Las Casas 1909; Saville 1921). Hernández reported that God the Father was *Içona* (*Itzamná*); the Son was *Bacab*, son of a virgin named *Chibirias* (*Ix-chebel-yax*, according to Seler); the Holy Spirit was *Ekchuuah* (Tozzer 1941:310). Tozzer also discusses a report of 1913 by Bartolomé del Granado Baeza which records saint names for three of the *Pauahtuns*. The bishop's letter of 1606 indicates that the naming of certain gods by the names of saints started early, and it continues to the present day (Gann 1918:46-47). Deities with saint names appear, however, to have retained their pagan functions and

characteristics. The bishop, of course, was well advised in condemning the practice.

The bishop's letter of 1606 was written in response to an inquiry from the Audiencia of Mexico, which in turn was prompted by a *royal cédula* of April 24, 1605, asking for information concerning the practice of idolatry in Yucatán "and why it is more prevalent in that province than in others." The bishop stated that it was not because of lack of instruction in the elements of Christian faith and doctrine, for he had personally examined some of the idolaters and they had given adequate answers to all questions of faith. It was his opinion that there were two major causes for the continued practice of the native religion. The first was the mild punishment that had been imposed, even in the case of the caciques and native priests. It is known, of course, that Landa used stern measures during the investigation of 1562. Although the latter investigation put an end to the practice of human sacrifice, the severe punishments and torture employed by Landa not only caused serious unrest in Yucatán, but also aroused unfavorable criticism in high Spanish quarters. Consequently, in later years the clergy tried another tactic, employing public or private admonitions or some form of mild punishment in dealing with the idolaters. As already noted, Dr. Palacio proposed to deal more harshly with the caciques and native priests than with ordinary offenders, but in general the local authorities apparently tried to cope with the situation without resort to stern measures. But this method had failed, for, as the bishop said, Indians who had been punished on other occasions had continued their idolatrous practices, "the cause of which, I understand, is the mild punishment they have received for this great offense against God." "It appears to me therefore that it would be suitable for Your Majesty to order . . . that the leaders and priests, especially those guilty of second offenses, should be given the most severe penalty."

The second cause noted by the bishop was the lack of compact Indian settlements, "because in all this diocese there is no well formed town; on the contrary, each household lives by itself scattered among the bush in such a way that a town of 100 citizens may occupy a district of half a league because of the scattering of the houses." This statement probably exaggerated the situation, but it indicates, nevertheless, that the policy of congregating the Indians into compact towns instituted by Tomas López in 1552 had not been effectively carried out, or that during the later decades of the sixteenth century there had been considerable laxity in regard to town organization and control. To remedy the situation the bishop recommended that effective measures should be taken to reassemble the Indians "in streets and squares surrounding

the church, so that in this way there would not be such freedom for their debaucheries and other sins, and so that they will be better indoctrinated."

The *definitorio* (governing council) of the Franciscans also made a statement on the subject which supported the bishop's views. The Franciscans, however, added another point of vital importance: the fact that the Indians of settled towns in northern Yucatán maintained contacts with the "gentiles" of the interior, with whom they carried on trade, selling them such articles as salt, knives, axes, machetes, and similar goods. As a result of this trade and commerce they learn the idolatry and ancient rites which they may have forgotten as a result of evangelical teaching." The Franciscans might also have added that the bush country of the interior was also a convenient place of refuge for groups of Indians who, for one reason or another, wished to escape Spanish control, civil or religious. Throughout the entire colonial period the Spanish authorities sought to bring the interior under effective control, but in the main they never achieved more than temporary success. The bush and forests of central and southern Yucatán were always a haven for Indians who wished to escape oppression, or to live according to the old native customs.

During the past year Mr. Roys has continued and nearly completed the transcription of a Maya manuscript known as the *Ritual of the Bacabs*. This document of 237 pages consists mostly of medical incantations, although some directions for treatment are also included. The last page is written, on the back of a printed Indulgence dated in 1779. Although much of the manuscript is not difficult to read, on many pages there are water stains or the writing has faded, so it has been necessary to make a preliminary study of the more legible parts in order to complete the transcription.

In spite of the late date of the manuscript, these incantations are practically free from European influence. With the exception of an occasional "Amen" and very rare mention of the Spanish *Dios*, no reference to the Christian religion has yet been found. "The four gods, the four Bacabs," who were prominent deities, are often invoked, and it is from these that the manuscript was given its title by its discoverer, William Gates. The Pauahtuns, believed to be wind gods, are barely mentioned. As might be expected, the Maya goddess of medicine also plays a prominent part; but she is usually cited in a twofold phase, as *Chacal* ("the red") *Ix Chel*, and *Sacal* ("the white") *Ix Chel*. Only once have we noted an *Ekel* ("black") or a *Kanal* ("yellow") *Ix Chel*. The distinction may indicate a reference to the four world quarters, to which these colors were ascribed.

A number of other deities are invoked or cited. We find the 13 sky gods known as *Oxlahun-ti-ku*, and the

nine deities of the underworld, *Bolon-ti-ku*, which are occasionally mentioned in the Books of Chilam Balam, but the others appear only rarely in colonial Maya literature.

Several times there is an invocation to the little-known *Colop-u-uich-ku*. The name strongly suggests a sun god, and in the Vienna dictionary he is described as "the principal god . . . from whom they said all things proceeded and who was incorporeal, hence they made no image of him." We also find a mention of *Kin-ich-kak-mo* ("sun-eyed fire parrot"), a more familiar deity associated with the sun.

The sky god *Itzamná*, usually considered the head of the Maya pantheon, also appears in these incantations. We read of "the home of the father (or lord?) of the sun, *Chac Ahau Itzamná*." This name could be translated as "great (or red?) lord *Itzamná*." There is an obscure reference to "the thigh of *Hun Itzamná*," and a *Kanal* ("yellow") *Itzamná* is also cited. Associated with *Itzamná* are the iguana (*huh*) and another lizard (*Itzám*).

Frequent accessories, apparently in the ceremonies which accompanied these incantations, were a green human figure of wood (*yax uinicil te*, or *che*) and a similar one of stone (*yax uinicil tun*). In the treatment of a sore foot, we infer that changing the dressing is symbolized by what is called changing the bed covers of these figures. These coverings are alleged to be the tails of the quetzal (*yaxum*) and the macaw. In this manner, states the healer, "I remove the great causer of pain."

The disease is often personified and is informed that 4 Ahau, or sometimes 1 Ahau, was the day of its birth. The healer addresses it with authority and threatens it. To one disease he says: "Thus I throw you down. I am your mother, I am your father; I cast you into the midst of the sea." To another he claims a similar relationship and condemns it "to the evils of the underworld."

Many of these incantations have a genuine poetic quality and abound in graceful figures of speech. In treating various feverish skin eruptions the healer states that he is cooling the throbbing pain with his red, white, and black fountains and with cenotes, forest ponds, and hailstones of these colors.

Some of the incantations are ordinary magic, such as charming a scorpion or cooling water while it is on the fire. The most interesting and poetical is that of the birth of the spider, which has been published by J.E.S. Thompson (1939b). Here a green wooden spider and one of stone appear to take the place of the human figures in the other incantations.

The language of this manuscript is often obscure, and a complete translation will be very difficult.

In view of J.E.S. Thompson's approach to the problems of hieroglyphic writing by seeking parallels be-

tween such texts and certain passages in the colonial Maya literature written in European script [Chapter 6.4], we have searched the latter for chronological expressions or figures of speech which might easily lend themselves to pictorial representation. Their precise significance is not always clear, since they have come down to us mostly in manuscripts of the eighteenth century. By this time the copyists, who occasionally interpolated their own comments had forgotten or become confused over some of the details of the old calendar system. We even find the katun explained as being a period of 24 years. The following excerpts have been selected from a series of yearly prophecies covering 20 years, which are recorded in the Books of Chilam Balam of Tizimín and Maní. They are given here as examples of phrases which we might expect to find expressed in hieroglyphic writing, but it does not, of course, necessarily follow that such will prove to be the case.

These prophecies begin with a statement of "the taking of *lac* of Katun 5 Ahau." The *lac* today is a shallow bowl, and the term has also been defined as a clay idol, but we infer it was an effigy bowl, possibly an incense burner. There are occasional references to the "burden" or "charge" (*cuch*) of the katun. In one of these the number 5, the coefficient of the day for which the katun is named, is said to be its burden; and we are reminded of a full-figure Initial Series inscription at Copán, although here it is not the coefficient which is represented as being the burden.

One of the year bearer's is "the day of setting in order the bird (*ch'ich'*) of the katun." Since we find elsewhere the "bird" of the day closely associated with its augury, the term probably has the same meaning for the katun.

For the tenth year there is a reference to the fan and bouquet of the ruler, presumably the god presiding over the katun, who "points his finger at the day he takes over his government." He is set up at his cup, (*luch*), on his throne or dais (*dzam*), his mat (*pop*), and his seat (*kanche*); and this establishment of the lord of the katun was very probably a chronological ceremonial.

For the year in which the last hotun begins we find a reference to the "binding of the burden of the katun." Here, instead of the coefficient, the burden appears to symbolize the destiny of the katun, which consists mostly of various misfortunes. This meaning is confirmed by the Motul dictionary. In the following year the burden is bound again, and the "rulers of the land" are said to be blindfolded. Whether earthly rulers or gods are meant is a little uncertain. Elsewhere in these Maya manuscripts the blindfolding of a deity appears to symbolize the loss of his power. Here it seems to indicate the approaching end of the katun, an event which concerned both gods and men.

At the end of these prophecies we are told that on a day 13 Oc "the katun is paced off" (*u chek oc katun*). This is evidently a play on the day name can also mean "foot." In the Codex Pérez, however, the "pacing off" of the katun appears to begin on the day Oc, which falls just 10 days before the end of the katun.

Mr. Thompson has noted a danger in this approach because of the uncertainty as to the language of the people who carved the inscriptions. A large proportion, though by no means all, are found in areas where either Yucatecan Maya or one of the Choloid languages was spoken at the time of the conquest. The latter comprise Chontal, Chol, and Chortí, and it has been shown that these three are hardly more than dialects of the same language, which, indeed, the sixteenth century Spaniards considered them to be (Scholes and Roys 1948, 1966, 1968; J. Thompson 1938).

Philologists have established a close relationship between Yucatecan Maya and Choloid, and it has long been known that for a person who knew one, the other was not very difficult to learn. Nevertheless, how close the resemblance was for practical purposes is a matter of some consequence. It is certainly closer than would appear from the comparative word lists that have been published, and to form some idea of this a comparison has been made between Becerra's large vocabulary of Palenque Chol (1937) and the Yucatecan Maya. Many words are almost identical and have the same meaning in both languages. In other cases the words are the same, but they have a slightly different meaning. Becerra's bush is defined as an ordinary gourd (*calabaza*), whereas the Maya *bux* (pronounced the same) in northern Yucatán was a small wild variety. There are also numerous instances where a Maya would understand a Chol term in spite of its difference from the word used in northern Yucatán. In Maya a skull is *tzek*, and although the Chol equivalent is *bukel jol*, it resembles the Maya *baac* ("bone") and *hol* ("head"). Similarly, the Chol word for heel, *yitkok*, would be understood by a Maya as meaning the bottom of the leg or foot. There are certain sound shifts, but it seems unlikely that they would cause much difficulty. For consonants the two most frequent shifts are those in which Maya *can* ("serpent") and *che* ("tree") correspond to the Choloid *chan* and *te* or *tie*.

A comparison of the first 400 words of Becerra's Chol vocabulary with their various Maya equivalents or near equivalents suggests strongly that a Yucatecan would either understand or have an approximately correct idea of the meaning of 50 to 60 percent of them. Available Choloid texts are few and brief except for the long Acalán Chontal narrative, which contains a very considerable variety of subject matter. Here the sentence structure is very similar to that of Yucatecan Maya. The tentative conclusion of this inquiry is that

whatever its origin, Maya hieroglyphic writing was probably adequate for the use of both these linguistic groups.

FRANCE V. SCHOLES,
RALPH L. ROYS, ELEANOR B. ADAMS,
AND ROBERT S. CHAMBERLAIN
History of Yucatán

YB 45:217-221, 1946

The volume on the history of the Chontal Indians of Acalán-Tixchel, on which Messrs. Scholes and Roys have collaborated, was completed during the past year. The work is now in press.

During the year Mr. Scholes and Miss Adams have also carried forward the documentary research for the general history of Yucatán and its environs in colonial times. Although the greater part of this work will deal with northern Yucatán, sections of it will also be devoted to developments in the interior of the peninsula and the many efforts to pacify the unconquered Indians in the regions bordering on the frontiers of Tabasco, Chiapas, and Verapaz. The documentary sources, printed and manuscript, dealing with the Indians of these frontier districts are numerous and have not been fully exploited by historians and ethnologists. In the present report, it may be of interest to give advance notice of an unpublished manuscript on the history of Verapaz, Guatemala, and adjoining areas compiled by Don Martin Alfonso de Tovilla, who served as alcalde mayor of Verapaz in the early 1630s. A complete account of this work, with translations of its more important sections, is being prepared for publication by Mr. Scholes and Miss Adams.

Tovilla was appointed to the office of alcalde mayor of Verapaz on December 18, 1629. The following year he sailed with the fleet for America, taking passage on one of the ships bound for Honduras, and finally reached Cobán, the administrative center of Verapaz, early in 1631. Fray Francisco Ximénez (1929-31, Bk. 4, Ch. 68) mentions Tovilla but tells little about his activities as alcalde mayor. From Tovilla's own account we learn that he had a keen interest in the history and customs of the Indians and made some effort to pacify

certain groups of Manché Chol on the frontiers of Verapaz. Little is known concerning his later career. His treatise entitled *Relación histórica dyscreptiva de las provincias de la Verapaz y de la del Manché de el Reyno de Guatemala*, is dated at Cobán, May 17, 1635.

The *Relación* is divided into two books, the first containing 26 chapters, and the second, 14 chapters. Extensive sections, especially those dealing with the early history of Verapaz, are taken largely from Remesal and have little merit. On the other hand, the chapters dealing with Tovilla's own activities and the descriptions of native life recorded in various parts of the work have genuine value.

Book 1, Chapters 1–6 record the story of Tovilla's journey to America in 1630–31. Here we find an interesting account of the long voyage to the West Indies, a description of the city of Trujillo in Honduras, and the narrative of the author's trip from Trujillo to Cobán by way of Santo Tomás de Castillo, Golfo Dulce, and the Río Polochic. After describing his arrival in Cobán, the author interrupts the account of his own activities to give a lengthy statement concerning the early history of Verapaz (Bk. 1, Chs. 7–23). As already noted, this account is based largely on Remesal. In Chapter 22, however, he includes the text of ordinances for the government of the Indians of Cobán formulated in 1625 by Juan Maldonado de Paz, oidor of Guatemala. This document throws light on native life and customs. In chapter 23 the author gives a brief account of "the fruits of the land and the festivities which the Indians observe."

On arriving in Cobán, Tovilla obtained information from the missionaries concerning the Manché Chol and other Indian groups on the frontiers of Verapaz. Missionary activity among these Indians was begun in 1603, and considerable progress was made during the succeeding quarter century. But conditions in the Manché district were far from stable, and Tovilla formed plans for the founding of a new settlement in that region as a means of imposing a greater measure of Spanish control. In March 1631 he went to Guatemala City to obtain authorization from the superior governmental officials for the enterprise. In Book 1, Chapters 24–27 we have a record of the events of this journey, a brief account of Guatemala City, and the texts of the orders issued by the captain general of Guatemala naming Tovilla commander of the proposed expedition to the Manché country.

In April-May 1631 Tovilla and a small group of soldiers advanced into the interior from Cobán. They were accompanied by Fray Francisco Moran, prior of the Cobán convent. On May 17 Tovilla founded a settlement named Toro de Acuña near the site of San Miguel Manché. Soon thereafter the alcalde mayor returned to Cobán (Bk. 1, Chs. 27–28; Bk. 2, Chs. 1–6).

During succeeding months Tovilla made a visitation of his province and adjacent areas. His account of this trip (Bk. 2, Chs. 7–12) includes data concerning various Indian groups on the northern frontier, an interesting account of the Lacandon, and also information on the Quiché. Toward the end of 1631 it became apparent that the new settlement of Toro de Acuña would need reinforcement, for the region was subject to attack by the Itzá. After considerable delay the captain general of Guatemala authorized Tovilla to take necessary measures. Before Tovilla's plans could be carried out, however, the Itzá raided the frontier, forcing the soldiers and Father Moran to withdraw in haste to Cahabón. Although Tovilla again appealed to the captain general, the latter refused to act until the matter was referred to Spain for decision. This apparently occurred in 1633, and it seems likely that Ximénez' account of a Manché rebellion in that year actually refers to these developments. Tovilla's account of Verapaz ends with this episode. The last chapters of the *Relación* contain a description of the coasts and ports of America (Bk. 2, Chs. 13–14).

As a historical source Tovilla's report is interesting chiefly because it records certain facts hitherto unknown concerning the Manché missions. The ethnological data scattered through the *Relación* have even greater significance. For purposes of illustration the following quotations are taken from the author's account of the customs of the Manché Chol:

These Indians of Manché have many idols. Three are their principal gods, which they call *Man Canam*, *Chuen exchel*. When [the Indians] perform sacrifice and celebrate feasts to them they set up a large bower (*enramada*) in an arroyo, and they paint themselves, the married men red and the youths black. They set up an altar in which the idol is placed. Then comes the priest, whom they call *acchu*. He wears painted vestments made of the bark of trees. On the sides of the altar are placed two wooden [an illegible word here] with shallow dishes full of incense. In another dish the priest collects the blood which all draw in sacrifice from their ears, arms, and thighs, and he offers it to the idol. Then all leave together, and in another place they become intoxicated with a very strong drink called *chicha*. Those who serve this drink are all maidens, adorned with feathers, strings of beads, and garlands. They are accustomed to spend two or three days in this drunkenness.

In view of the fact that other early writers state that the Manché Chol did not have idols, the foregoing passage has considerable interest. The names of the "three principal gods" are recorded exactly as they

stand in the manuscript. It may be noted in passing that Moran's dictionary of Chol gives the term *Mam* for idol. Thompson (1938:599) has called attention to another refer ceremonial intoxication among the Manché Chol.

Thompson (1938:599) has noted that other early accounts contain no mention of a Chol calendar, "except that the new year celebration at Dolores was called *Chuntal Cutaz*." Tovilla describes the Manché calendar as follows:

[The Manché] divide the year into 18 months of 20 days each, and the 20 days all have their name . . . The month is called *uinal*. The 20 days are divided into four divisions of five days each, and the first four days of these four divisions change position annually to begin the months. According to what [the Indians] say, [these four first days] are those which direct the way (*toman el camino*) and bear the burden of the month (*cargan el mes*), changing in turn. These 18 months comprise 360 days, at the end of which are five which they call [days] of great fasting, days which have no name. With these five days are completed the 365 days [of the year]. The only error I have found in this count is that [the Indians] are ignorant of the leap years. This is not surprising, since for so many years we erred in this until the Church corrected it, adding a day every four years in the month of February because of the six hours by which each year exceeds 365 days. In the count of the Chol these 18 months end on June 28 . . . and then come the five days of great fast. This lasts until July 3, and it is a vigil of great veneration among them. Thus on July 4 begins the first day of the year according to their count.

From Tovilla's date July 3 one must subtract 10 days to reduce it to Julian. If 21 days are added from the elapsed leapdays, not recorded in the Maya calendar, the new year of the Chol would have fallen on July 14, 1553 (Julian), whereas Bishop Landa gives the start of the Yucatec year, for what can be deduced to have been 1553, as July 16 (Julian).

In view of the discrepancies which occur in the parts of the books of Chilam Balam relating to chronology and history, Mr. Roys has undertaken a comparative study of these manuscripts. Although it is evident that they contain many extracts from earlier manuscripts, nearly all of them apparently were compiled between the middle and end of the eighteenth century. Besides being of linguistic value, they serve a double purpose. Not only do they furnish a very considerable amount of ethnological and historical material for the study of the preconquest Maya, but they are also valuable for the colonial history of Yucatán, since they contain an admixture of European ideas and in-

formation which help greatly in making an appraisal of the acculturation of the Yucatecan Maya in the eighteenth century.

Some of the ancient lore recorded in these books appears to have been copied verbatim from earlier sources which show little Spanish influence, but much of it is interspersed with explanations, comments, and possibly even alterations by the later compilers. This is not always a defect. Sometimes the copyist explained obscure expressions and statements, which would otherwise be difficult to understand. Only too often, however, the interpolations are confusing.

A large number of the compilers of these manuscripts were more concerned with European lore of the sort found in the contemporary Spanish almanacs than with their own customs and traditions. The Book of Chilam Balam of Ixil, which probably dates from the late eighteenth century, is an excellent example of this tendency. Of its 88 pages, a little more than half contain copies of Maya translations of European material. There is a Catholic calendar, which is not translated, giving the days of each month, together with the pacts and dominical letters. Except for a few church festivals, the saint for each day is named, which was no doubt useful in selecting names for children. Accompanying this calendar is a dissertation in Maya on the European zodiac. Beneath a picture of each sign is the usual information, found in European almanacs, such as the day when the sun enters the sign, the number of stars in it, the hours of daylight and darkness, and other information for the guidance of a person born, under this sign. To this are added a chart with some tables, and other material on zodiacal anatomy, so that a healer might avoid bleeding any part of the body while the sun is passing through the sign of the zodiac ascribed to that part. Since bloodletting was a traditional remedy among the Maya, it is easy to understand their interest in this matter in colonial times. We also find a diagram and explanation in Maya of the medieval cosmos. The remainder of the part of the book which is European in content consists of Maya translations of sacred history. These are based on Genesis, but they contain a number of details which are not recorded in that book. Additional material of this sort, including passages from a popular Spanish romance dealing with astrology, is to be found in other Books of Chilam Balam, especially those of Kaua and Maní, although the latter two differ from the Ixil in that they contain more of the old native lore. That so much European material was translated into Maya is evidence of the extent to which a large and important element of the native population had become Hispanicized in spite of their ignorance of the Spanish language.

Nearly one-half of the Ixil manuscript is devoted to material which is essentially Maya, but modified by

European ideas. Here we find a correlation of nine months of the European calendar with the corresponding Maya days. A similar calendar was adapted, by Pío Pérez to the years 1841–1942 and published a century ago (Stephens 1843:1:449–458), and others occur in most of the Books of Chilam Balam. They contain weather predictions, prognostics of “good” or “bad” days, warnings of sickness and death, and various other portents, some of which are very difficult to translate. There is also a faulty correlation of the Maya *uinals*, or 20 day months, with the native day names. At the end of the Ixil manuscript are 27 pages of medical prescriptions. They are ascribed to a Moorish physician, a slave of the Cid Campeador, but they are largely Maya in content, although they contain a sprinkling of European remedies, and a good many names of plants and diseases are given in both Spanish and Maya.

There are only a few pages in the Ixil of material that is purely Maya. A little of this is astrology and the remainder is concerned with Maya chronology. There are two of the so-called calendar wheels, one of which represents an alleged “katun” of 13 years. Apparently this part of the book was copied from an earlier Maya manuscript written in 1701, but the errors strongly suggest that the Ixil copyist did not understand his subject. The inference is that by the last quarter of the eighteenth century many people were losing their former interest in the Maya sciences and historical traditions. This was not yet everywhere the case, however, as we see by comparing the Ixil manuscript with the Book of Chilam Balam of Chumayel, written in 1782. Here, it is true, there are a few translations or paraphrases of Spanish material but most of the book consists of Maya rituals, catechisms, prophecies, historical narratives, and chronicles, although we find in places some admixture of European ideas. The selection of the material in the Book of Chilam Balam of Tizimin is even more conservative and it contains fewer references to things Spanish, but it was probably composed at least a generation earlier than the Chumayel. The book of medical incantations known as the *Ritual of the Bacabs* is almost entirely pagan in character, although it was actually written no earlier than 1779.

The last important Book of Chilam Balam is the Kaua, written at about the end of the eighteenth century. It contains medical prescriptions, prophecies, and Maya astrology, and there is a rather unsatisfactory explanation of Maya chronology written in Spanish. A large part of it, however, is devoted to European astronomy and astrology and to the Christian religion.

The conclusion Mr. Roys has drawn from this study is that, valuable as these sources are for the study of Maya civilization, in their present form they come down to us from the hands of writers who were removed by at least two centuries from the Spanish con-

quest, during which time they were subject in varying degrees to European influences, and the chronological information and historical traditions they present should be used with considerable caution.

Mr. Chamberlain, who served as cultural attaché in the United States Embassy in Guatemala for four years (1941–45), resumed work as a staff member of the Division on October 1, 1945. His volume on the conquest of Yucatán is now nearing completion. He has also written a large part of a supplementary study dealing with the Adelantado Francisco de Montejo as governor of Higueras-Honduras, 1535–39. Two shorter papers, one relating to the early history of the town of San Miguel in southern Salvador and the other to the government of Montejo in Chiapas, should be ready for press in the autumn of 1946.

9.25.

RALPH L. ROYS

History of the Maya Area

YB 46:197–198, 1947

During the past year the comparative study of the Books of Chilam Balam has been continued. Especial attention has been given to the *Codex Pérez*, and a guide to this manuscript has been prepared to accompany the reproduction in the Peabody Museum of Harvard University.

The *Codex Pérez* consists of extracts which J. Pío Pérez copied from various Maya manuscripts, apparently during the second quarter of the nineteenth century. A large part of it was taken from the lost Book of Chilam Balam of Maní. There have been transcriptions, but only in recent years was Dr. S. G. Morley able to obtain a photograph of the original for the Carnegie Institution of Washington.

The first third of the manuscript is composed largely of Maya translations of European astrological and calendrical material [Chapter 9.24], which appealed to the interests of the more Hispanicized element of the Indian population; but most of the remainder is devoted to the native lore. The *Codex Pérez* covers a wide range of Maya learning and pays much attention to the augural or divinatory aspects of the Maya calendar. Here are predictions of the coming of the Spaniards and the new religion, prophecies for the

tuns or years, and others for the 20-year periods called katuns with their valuable historical allusions. Of especial interest are the famous Maní Chronicles, several isolated historical narratives, and a version of the creation story differing in some respects from any that has been published. As in other Books of Chilam Balam, we find indications of the close association between history and prophecy in the Maya mind. One passage presents an important aspect of native Maya astrology, and there are several long explanations of Maya chronology. In spite of some chronological errors, these disquisitions add considerably to our knowledge of the native terminology and the point of view of the Indians who were endeavoring to preserve the old traditions. Besides the material not found elsewhere, there are parallels of passages in other Books of Chilam Balam; but in general the Codex Pérez versions are fuller and furnish more details.

In a previous report [Chapter 9.23] attention was called to chronological concepts expressed in certain prophecies in the Books of Chilam Balam of Tizimín and Maní. For the better understanding of this aspect of Maya science, a tentative translation has been made of a series of prophecies for the 20 tuns of Katun 5 Ahau alleged to begin in 1593. In its present form the series is the work of eighteenth century compilers, and the chronological setting is incorrect; but the greater part of the content appears to have been copied from earlier manuscripts. Although it seems plain that the prophecies really apply to the tuns, more emphasis is placed on the year-bearers. It is true that pessimism predominates in other Maya prophecies, but here the news is almost invariably bad. The language is often symbolic. Mythological allusions are frequent, but only rarely are they to the better-known and more important deities. A number of the names, such as *Chacuayab-xoc* (Great Demon Shark?) and *Chac-mumul-ain* (Great Muddy Crocodile?), suggest fabulous monsters. Fauna names are sometimes preceded by a numerical coefficient, such as *Ah Uucte-cuy* (7-Owl) and *Ah Uuc-ch'apat* (7-Centipede). These may be mythological personages, but the close association of the name. *Ah Buluc-am* (7-Spider) with Montezuma suggests that it was considered to be the Maya name of the latter.

During this period work has been done on collecting and cataloguing material from sixteenth century sources for a study of the political geography of the Yucatán peninsula at the time of the Spanish conquest, a joint project of Dr. Scholes and Mr. Roys. Time has also been devoted to reading proof of the history of the Chontal Indians of Acalán-Tixchel.

9.26.

FRANCE V. SCHOLES AND
ELEANOR B. ADAMS
History of the Maya Area

YB 46:198, 1947

Work has been done on collecting and cataloguing material from sixteenth century sources for a study of the population and political geography of the Yucatán peninsula, a joint project of Mr. Scholes and Mr. Roys. This work has included the study of data previously assembled, and the investigation of additional documentary series, chiefly encomienda papers and proofs of services of conquerors, soldiers, and early settlers of Yucatán. The collection of the data is now nearing completion, and during the coming months the final study should begin to take form.

Miss Adams has carried forward her investigations of the foreign corsairs who scourged the coasts of Yucatán in the sixteenth century. The spadework research for this study, which has necessarily included the study of a wide range of supplementary sources in addition to those directly relating to events in Yucatán, is now virtually complete. Miss Adams will spend a considerable part of the coming year in writing up the data as a separate monograph.

These two studies will help to lay the foundation for the general history of Yucatán in the sixteenth century, the major project of Mr. Scholes at present. For this larger work some documentary research remains to be done, but the major series of documents have been rather thoroughly surveyed or extracted. The general plan of the history has also been worked out in some detail, and outlines have been made for several chapters.

Finally, considerable time has been devoted to the reading of the proof of the history of the Chontal Indians of Acalán-Tixchel, now in press.

9.27.

ROBERT S. CHAMBERLAIN
History of the Maya Area

YB 46:198–200, 1947

Mr. Chamberlain's work has consisted of an investigation of the Spanish conquest period, roughly 1517–

50, in Yucatán, Tabasco, Honduras, Chiapas, and adjacent territories. His writing is based primarily on extensive research in documents existing in the Archivo General de Indias de Sevilla, the Archivo Histórico Nacional, Madrid, the Archivo General del Gobierno, Guatemala City, and to a lesser degree in the Biblioteca Nacional, Madrid, the Archivo General de Simancas (Spain), and the Archivo General de la Nación, Mexico City. This research has helped to close important gaps in the history of the former Spanish provinces named above, to correct earlier accounts, and to re-evaluate, or evaluate for the first time, the course of events.

Mr. Chamberlain's research has made possible the preparation of two major works, one on the conquest and colonization of Yucatán, and the other on the conquest and colonization of Honduras, for publication by the Carnegie Institution of Washington, and brief monographs and articles for publication by the Carnegie Institution of Washington and by various historical journals. Because of the interlocking nature of much of the documentary source material, the preparation of the manuscripts of the two major studies was carried on concurrently, the manuscripts being completed some months apart.

The principal new contributions to Spanish colonial history resulting from Mr. Chamberlain's work have been: 1. The history of the conquest of Yucatán has been corrected, amplified, and reinterpreted. 2. The history of the conquest of Honduras has been fully told. Five unknown years, 1539–44, important for the governmental evolution of Honduras and for the extension of the conquest, have been added to the history of the province. The conquest of Higueiras, the western and, in the colonial period, the most important part of Honduras, has been more fully told, and new interpretation has been given to the early history of the province as a whole. 3. Four years have been added to the history of Chiapas, 1541–44, when Francisco de Montejo, who was also Adelantado of Yucatán and Governor of Honduras, was governor of that province. This has been done in a brief monograph which is being published as Contribution 46 in the *Contributions to American Anthropology and History* (Chamberlain 1948b). 4. Through the histories of the conquest and colonization of Yucatán and Honduras, Francisco de Montejo has been revealed as one of the truly great Spanish conquistadors and administrators. Montejo's career has hitherto been neglected. He was a man of great stature and vision, an empire builder in the real sense. Mr. Chamberlain is drawing up an outline on which to base a biography, as such, of Montejo.

In addition, on the basis of documents from the Archivo General del Gobierno, Guatemala City, it has been possible for the first time to give an account, even

though a very brief one, of the early history of the town and province of San Miguel, now the southern part of the Republic of El Salvador.

During the period which Mr. Chamberlain has had under study, fusion of European culture, as represented by the Spaniards, with native New World cultures, and mixture of European and Indian races not only began but progressed rapidly. Spanish governmental, religious, economic, and social forms, institutions, and attitudes were speedily imposed on the Indians. At the same time the Indians sought tenaciously to cling to their own cultures. It is this continuous and fundamental clash and fusion of European and native American cultures and races which have given most of the Spanish American countries their past, present, and future form and aspect. It scarcely need be pointed out that greater knowledge of the past and present of the countries and peoples of Latin America is becoming increasingly important in view of the fact that the United States is now forging more closely than ever before its political, economic military, and cultural bonds with the other nations of the western hemisphere.

9.28.

RALPH L. ROYS

History of the Maya Area

YB 48:239–241, 1949

During the past year, *The Prophecies of the Maya tuns or years in the Books of Chilam Balam of Tizimín and Maní* has been completed for publication, and some time has been spent in reading the proofs of this Contribution and the *Guide to the Codex Pérez*.

The source material for the history of Mayapán has been assembled and translated into English from the Spanish and Maya, where such translations were not already available. The sources quoted are accompanied by commentaries, in which they are compared and discussed and some of the more important implications are noted.

There is fairly good evidence that the area ruled by Mayapán included most of the Yucatán peninsula north of Campeche, although the evidence for the northeast and east coasts is conflicting. Nothing has been found about Campeche in this connection.

Taken as a whole, the references to Mayapán indicate the need of a new interpretation of the source

material. In the past, historical reconstructions have been based principally on the chronology of the Maya Chronicles in the Books of Chilam Balam, but with unsatisfactory results. Uxmal, Chichén Itzá, and Mayapán were long considered to have been contemporary capitals in Yucatán, but archaeologists have found that their more important buildings occurred at three different periods in the order named. J.E.S. Thompson has noted the weakness of this chronology, and a comparison of all the historical sources suggests that the accounts by Gaspar Antonio Chi offer a framework in which Landa's narrative and the episodes related in the Chronicles could more easily be reconciled with the archaeological findings. This compilation also presents evidence that the important Xiu family became a political factor in northern Yucatán only in the late fourteenth or early fifteenth century, and not in the eleventh century as previously believed.

The late winter and spring were spent in Yucatán continuing previous studies of the political geography at the time of the Spanish conquest [Chapters 9.14 and 9.17]. One purpose of the present survey was to see what indications exist that the modern towns are situated at conquest sites of the same names; another was to locate historic sites that are no longer shown on the maps.

A search was also made for conquest sites which would be likely sources for the recovery of late preconquest and early colonial pottery. Although ceramic sequences have been established from very early times down to the fall of Mayapán, about the middle of the fifteenth century, it has been difficult to find sherds which could be identified as belonging to the period following that time. It seems possible that this is partly due to a Spanish policy of replanning the Indian towns, by which it is known that the houses were concentrated nearer the church and central plaza and for the first time arranged along regular streets with smaller yards and gardens than previously. Several centuries of occupation in colonial and modern times have further aggravated this disturbance of the topsoil containing the sherds which had accumulated during the last pre-Spanish period and that of the conquest. For this reason particular attention was paid to historic sites from which the people had been removed at a fairly early period. A few of these, Hunacti, Calotmul, and Cauich, had been located during previous visits to Yucatán. This, year four more were visited and identified: Kanchunup near Sotutá, Tecoh near Izamal, Tuchicaan near Maxcanú, and Quizil near Uman. Hunacti and Kanchunup were subject to European influence for the shortest time, since they were left deserted prior to 1582, and very possibly as early as the 1560s. The churches of these two towns, as well as at Tecoh and Quizil, were of an early type. Only the

chancel, sacristy, and priests' quarters were built of masonry. There was no nave, and the congregation evidently occupied an open structure of pole and thatch, called a *ramada*, of the sort described in various sixteenth century Spanish reports. It seems probable that all four sites were abandoned at an early date. Since there are cenotes at three of them and a pond of potable water at Tecoh, they would appear to be promising sources of late preconquest and early colonial pottery. Tuchicaan and Tecoh are of especial interest, since both played an important part during the Spanish invasion of Yucatán. There are still extensive Maya ruins at all seven sites mentioned above except Kanchunup and Cauich.

Indications exist that a very large number of the colonial churches in Yucatán were built partly of hewn blocks taken from ancient structures in the immediate vicinity, although such material apparently was sometimes supplemented, as at Kinchil and Kaua, by hewn stone from other sites as far as 6 km distant. Two of the oldest convents, at Mérida and Izamal, were built on the summits of fairly high substructures, and in the northwestern and the northern parts of the state, as far east as the vicinity of Izamal, a great many churches are set in spacious patios which are raised from 1 to 2 m above the level of the town. In such cases this platform appears to have been constructed from the rubble fill of a large Maya substructure. Possibly it consisted partly of the flattened base of a pyramid and was completed from other neighboring mounds. There is some evidence of this at Hunucmá and still more at Chuburna. Raised platforms on which the churches stand are much rarer in the Sotutá and Valladolid areas farther east, and in the former Xiu Province of Maní to the south.

These raised church patios are frequently enormous structures, although they probably average only about 1.5 m in height. Roughly paced off, those at Hunucmá, Kinchil, Hocaba, and Humun have an average surface of about 8,000 sq. m. The platform at Humun is 3 or 4 m in height, but here it is partly formed of a low rocky knoll. Nowhere did there appear to be a depression from which this material might have been excavated. There are still many large Maya ruins in northern and northwestern Yucatán, but this use of the substructures for church platforms probably explains why they are not so numerous today as would appear from the sixteenth century Spanish reports. In spite of the important fisheries and salt industry in former times, agricultural conditions in northwestern Yucatán are such that it is difficult to explain the great building activities which evidently existed. Apparently there was a highly developed social organization over a very long period of time, and in this connection it seems relevant to note that some sherds gathered at

Caucel, when submitted to Dr. G. W. Brainerd, were identified as corresponding in age to the Chicanel phase at Uaxactún.

In a number of towns, where the site of the church is raised but little or not at all above the surrounding area, some of the old pyramids or other substructures were left standing in the immediate vicinity. This has been recorded of the cathedral at Mérida and the church at Motul. It is still the case at Ucú and Caucel, both of which might be considered sites of some promise for recovering sherds of the conquest period. Other instances can be cited at Yaxkukul, Acanceh, Sotutá, Dzan, Chapab, and Teabo. At Sotutá a large substructure near the church is surmounted by a fortified colonial building. Similar remains are also to be seen at Chicxulub, Ticul, Oxkutzcab, and near Tekax, but like many others reported from Yucatán towns, they lie at some distance from the church and the center of town.

Visits were made to the ruins at Aké, Acanceh, Izamal, Uxmal, Chichén Itzá, and Mayapán, and to the town of Champotón, all of which figure in the historical legends of the Books of Chilam Balam. At the time of the Spanish conquest Champotón was a large and commercially important town with many stone buildings. Although the architectural remains are scanty, there are still a number of scattered drums of cylindrical columns. They are rather roughly hewn and are reminiscent of those at Mayapán. Surface sherds are abundant in the streets, and the gullies which intersect the town seem to offer some promise of stratified deposits.

9.29.

ROBERT H. BARLOW

History of the Maya Area

YB 49:206–207, 1950

In the search for the missing fragments of the Maya record, one obvious approach seems to have been ignored. The collection and comparative study of folktales and beliefs in the Maya language have scarcely been attempted, despite the evidence of a 100 years of study to the effect that old religions and histories wear down in time to seemingly idle tales. No single old man, probably, is going to tell us the precise meaning of a frieze at Chichén Itzá, but a number of narratives

from a number of old men, accumulated and worked together in accordance with the Finnish technique, will certainly throw some light on the movements of peoples and concepts in prehispanic Yucatán. That very old materials survive orally is evident: in Guerrero State, Barlow has heard a witch woman pray in Nahuatl to the Thirteen Heavens; as recently noted by Professor Miguel Barrios E., the Nine Cardinal Points survive in agricultural ceremonies of Colima; and in the high Sierra Madre del Sur a detailed migration legend at least 700 years old is familiar conversation among the rustics. The present work in the Maya or Yucatecan language is aimed at the compilation of all folktales, beliefs, and traditions not evidently European, for the reconstruction of their prototypes.

In language study, the following approach has produced in the year since Barlow entered the field, the knack of conversing adequately. With the collaboration of a native speaker who has had training with the Summer Institute of Linguistics, a series of dialogue units on the model of the U. S. Army wartime language-teaching projects was blocked out, and the collaborator worked these up with grammatical commentary. Together with this introduction to the tongue, an infinitely more rewarding one than plowing through Latinizing grammars of centuries back, a series of texts on themes ranging from how to kill an armadillo to the folktales referred to was acquired from informants hailing from the regions of Peto, Chichén Itzá, Tekax, and Motul. It has seemed wise to await greater fluency in Maya before undertaking trips to the wholly monolingual zones, where the take should be rich indeed. Field trips to Yucatán were made in May 1949 and June 1950.

Published folktales from Yucatán are nearly all in Spanish or English and are nearly all concerned with European themes, apart perhaps, from a scrap collected by Berendt about the time of Maximilian and republished with such assiduity that one might think there were no live Maya and no living oral tradition to explore. It is improbable, according to D. Juan Martínez and other eminent students of the old texts, that much in the way of historical documents remains unknown in Yucatán.

9.30.

RALPH L. ROYS

Documentary Research

YB 50:245–247, 1951

During the past year the pre-Spanish history of Yucatán has been investigated from the standpoint of the historical allusions in the katun prophecies in the Books of Chilam Balam. Among the Maya, history and prophecy were closely associated; indeed, the same word is sometimes defined as a history, sometimes as a book of prophecies. This was evidently because what occurred in one katun was expected to recur in another of the same name. A katun contained a little less than 20 years, and the cycle, or katun round, covered about 256 years.

Our knowledge of the history of Mayapán is very incomplete. We have an excellent account of its government and customs; there is a brief mention of the founding of the city; something more is recorded about the later years preceding its fall and destruction. This leaves a gap of perhaps 160 years of which we know little. About all that we have been told is that there was a joint government over a wide area; a group of newcomers called the Xiu were given a share in the government; and the Cocom, the most powerful of the rulers, introduced Mexican allies from Tabasco and oppressed the people. Consequently any additional information that we can glean from the prophecies is of considerable importance. In the latter sources there are also many references to religion, especially in its relation to chronology and astronomy, but this sketch will be confined to the historical allusions.

Most of the versions of these 13 prophecies begin with Katun 11 Ahau. Each katun is partly designated by a numerical coefficient two less than the preceding, 13 being considered two less than two, and 12 two less than one. One version, however, resembles several of the chronicles in beginning the cycle with a Katun 8 Ahau, and the latter system will be followed here.

The prophecy for Katun 8 Ahau contains references to the expulsion of the Itzá from Chakanputún, probably Champotón; to the arrival of Kinich Kakmo, elsewhere reported to have been the founder of a dynasty at Izamal; and to the destruction of Mayapán. The time of the first two events has been a matter of controversy. It could have been either in 948 or in 1204, but the latter date seems preferable. The fall of Mayapán occurred in the katun which ended in 1461. For Katun 6 Ahau, which could have ended in 1224, there is an account of insolent-faced rulers whose speech is

shameful. We are told of purse snatching and other minor violence; the *halach uinics* of the town are beheaded. Finally, it is stated: "Very evil is the rule of the three occupants of the mat and throne on the dais." This number is rare for administrative divisions in Yucatán, and we cannot but be reminded of Landa's account of three brothers who ruled at Chichén Itzá not long before the coming of Kukulcan, although he states that only two of them acted badly and were killed.

In Katun 4 Ahau, the second after the Chakanputún episode, we read of the arrival of Kukulcan and the Itzá. That of Kukulcan is said to be for the second time, which would account for earlier representations of this culture hero at Chichén Itzá. There is also, however, a reference to a well known epidemic which occurred in a later Katun 4 Ahau (1480–1500). Katun 2 Ahau is associated with the first coming of the white men in the decade preceding 1520, but even this is compared with the earlier arrival of the Itzá. One of the Chronicles states that the town of Mayapán was founded in a Katun 13 Ahau and the only katun of that name consistent with the ceramic evidence ended in 1283. Unfortunately no allusions to this event are apparent in the prophecies, but they contain references to an erotic cult of the *plumeria* flower and to some ill-behaved "two-day" rulers who do not respect their parents. These were evidently the Itzá, who were somewhere in the picture at the time.

The two following prophecies, for Katuns 11 and 9 Ahau, are chiefly concerned with the coming of the Spaniards, the building of Mérida, and missionary activities (1539–79). There are, however, brief allusions to the *plumeria* cult and moral laxity at an earlier period.

In Katun 7 Ahau, ending presumably in 1342, the Itzá, who had settled at Chichén Itzá a century before, are extending their influence and corrupting people everywhere with their erotic *plumeria* cult. They are lewd rascals who "twist their necks, they twist their mouths, they wink the eye, they slaver at the mouth," and they even make light of the *halach uinics*. In 5 Ahau (1342–1362) things have gone from bad to worse. The Itzá are now actually ruling the country, and perversity is open and unashamed. The principal men have turned to sorcery and are transforming themselves into lynxes. This condition continues throughout most of the following Katun 3 Ahau, until there is a political upheaval, apparently about 1382, when the evil rulers are beheaded.

Soon after, early in Katun 1 Ahau, an unidentified ruler visits a savage retribution upon the local *batabs* who had achieved their position under the evil rulers. This is confirmed by two passages in the Books of Chilam Balam of Chumayel, which tell how it came about. The remainder of the katun, however, is a time

of troubles, and we read briefly of affliction by the Canul. There is evidence that the Canul, or Ah Canul, were the so-called Mexican mercenaries introduced into Mayapán by the Cocom rulers, but it is only here that we find some indication as to when this occurred. Later, we are told, the Ah Canul were the guardians of the gates at Mayapán, but Maya literature has little or nothing to say about the Cocom. One might think from these prophecies that this was the end of the Itzá, yet we learn from other sources that some of them remained at Chichén Itzá until the Katun 8 Ahau which ended in 1461. Since they were expelled by a group from Mayapán, the date must have been prior to the fall of the latter capital; but we have excellent evidence that Mayapán was destroyed in this same Katun 8 Ahau.

The Katun 12 Ahau immediately following 1 Ahau was noted for its benevolent rulers, peace, and good morals. Historical references seem to be lacking for the succeeding Katun 10 Ahau, except that there was drought and famine. This represents the end of the cycle. For the following Katun 8 Ahau, as we have already seen, there is a brief mention of the fall of Mayapán. Fortunately Landa and the Maya Chronicles tell us more about this event.

It is hard to tell how accurate a record of events is represented by the historical allusions in these prophecies. It seems very probable that they reflect the beliefs of the sixteenth century Maya concerning their history during the 350 years prior to the Spanish conquest. That something was known of the preceding period seems certain from a brief but convincing report by an early native informant, but it is difficult to identify any reference to that period in the prophecies that have come down to us.

9.31.

RALPH L. ROYS

Historical Geography and Documentary Research

YB 51:271, 1952

The late winter and spring were passed in Yucatán, in an investigation of the boundaries of the former native states at the time of the Spanish conquest, for the purpose of compiling a historical geography covering that period. A number of villages and rural sites on or near

these former political frontiers were visited, and especial attention was given to two of these borders. One was the eastern limit of the so-called Province of Ah Canul, which extended from a little above the latitude of Campeche to Punta Kopte on the north coast. The other was the line separating the Province of Ah Kin Ch'el on the west from those of Chikincheel (sometimes called Chauaca) and Cupul on the east. Information regarding the latter was obtained at Temax, Buctotz, Dzilam González, and Dzilam Puerto.

Associated with these investigations was a search for more sites from which people were moved in very early colonial times and concentrated in towns, where they could more easily be supervised (YB 48). Calkini, for example, was little more than a village at the time of the conquest, but it soon became a large and important town where a convent was founded. From a native Maya chronicle we know the names of the former settlements from which it was recruited, but they no longer appear on the maps. This problem was largely solved after a visit of some days at Calkini and a tour of the surrounding country, thanks to the cooperation of the local professor, the mayor, and the librarian. Similar inquiries were pursued at Tizimín with some success, but, less than at Calkini.

Owing to the kindness of Mr. Don Drury, it was possible to establish headquarters at Colonia Yucatán in the northeast corner of the state and visit the surrounding area. One trip was made to El Cuyo, where a modern lighthouse surmounts an ancient stone mound of considerable size on the sand dunes by the sea. Not far to the south is Laguna Xuaca, from which the important conquest town of Chauaca took its name. Extensive ruins exist at Kantunilkin in Quintana Roo to the east, including one pyramid containing a descent beneath a stepped roof to a series of very narrow vaulted apartments in the heart of the substructure. Several days were spent at a large ruined site close to Colonia Yucatán, assisting Lawrence Roys in making a preliminary plan of the remains. Although no name is now known for this site, its location and a garbled name on three of the older maps give reason to believe that it was the large and important town of Sinsimato, visited by Montejo during his first expedition into the Yucatán peninsula in 1527–29.

During the past year *The Maya katun prophecies of the Books of Chilam Balam, Series I* has been completed for publication. Some time has been spent in reading the proofs of *Conquest sites and the subsequent destruction of Maya architecture in the interior of northern Yucatán*.

9.32.

RALPH L. ROYS

Historical Geography of Yucatán

YB 52:292–293, 1953

During the past year Roys has been engaged in compiling a historical geography of Yucatán as it was at the time of the Spanish conquest. The boundaries of the independent native states have been determined and mapped so far as possible. In most cases the towns which they comprised can be identified with considerable certainty, and it is often feasible to make a rough estimate of their populations.

The larger towns were composed of subdivisions, each of which had its own name. Sometimes the first Spaniards named a town for one of these subdivisions in their reports; but the local convent or church was later built in another, and thereafter the town was named for the latter.

The Maya documents and early Spanish reports furnish the pagan names of a good many of the ruling chiefs. These have been noted; when they could not be ascertained, it has often been possible to give the later names of caciques or town governors, most of whom were either the rulers at the time of the conquest or their sons or grandsons. Many of these names were recorded in 1565 and 1572.

In colonial times the pre-Spanish patronymic was preserved as a surname, preceded by the baptismal name. The original population was composed of something over 260 exogamous patrilineal name groups, some of which were much larger than others. Their social significance was obviously important, but we know little about them, except that the members of each usually felt a certain personal responsibility for one another, and at least three groups had their own patron deities, possibly deified ancestors. Roys surmises that the latter was true of most of them. Their distribution in the various territorial divisions is of interest. Apparently the political importance of a name group did not necessarily depend on its size for the patronymics of the ruling families were sometimes comparatively rare, even in the states where they ruled.

It is hoped that this study will furnish a comprehensive picture of Yucatán as the Spaniards found it, part of which, heretofore, has been available only in untranslated Maya manuscripts or unpublished Spanish reports of the sixteenth century.

9.33.

PEDRO CARRASCO

Ethnohistory of Yucatán

YB 52:293, 1953

In preparation for research on the ethnohistory of the Yucatán Maya in preconquest and colonial times, Carrasco made a short trip to Mexico City and Yucatán. Besides visiting the main archaeological sites in Yucatán, he worked at the Archivo General de la Nación in Mexico City, and in Yucatán at the Archivo General de Gobierno and Archivo de Notarías in Mérida, and in some parochial archives.

A number of documents in the Archivo General de la Nación refer to the *visita* of García de Palacio (late sixteenth century). Like the published report on Cozumel, they offer important material for the social organization of this period. Together with other already published materials, they provide a basis for an ethnology of the Maya at the end of the sixteenth century.

Various papers in the Archivo General de la Nación, Archivo de Gobierno, and Archivo de Notarías contain data on land tenure in Indian villages.

Local government in Indian villages and the late ending of the encomiendas in Yucatán, and the situation of the Indian workers, are also well documented in material in the Archivo General de Gobierno and Archivo General de la Nación.

Parish archives have documents on the *cofradías* during the colonial period, a very interesting one being found in Uman. There is also information on the colonial caste system, and of course abundant demographic records. A special possibility in using parish archives is that of studying kinship organization from birth and marriage records. The books seen on this trip start late in the seventeenth century, but a more thorough search might yield older material.

Copies were made of some documents in the Archivo General de la Nación.

10.0. PHYSICAL ANTHROPOLOGY

10.1.

GEORGE C. SHATTUCK

Report on the Yucatán Medical Expedition

YB 28:301–303, 1929

At the suggestion of Carnegie Institution of Washington the Yucatán Medical Expedition was organized by the Department of Tropical Medicine of the School of Public Health of Harvard University. It was financed jointly by the Institution and by the Department. The Expedition, making its headquarters at Chichén Itzá, worked under the auspices of the Carnegie Institution. The members of the Expedition were Dr. G. C. Shattuck, director, Dr. Joseph C. Bequaert, entomologist, and Dr. Jack H. Sandground, helminthologist, from the Department of Tropical Medicine; and Dr. Kenneth Goodner, bacteriologist from the Department of Bacteriology. Mr. Byron L. Bennett served as laboratory technician. Members of the Expedition, except Dr. Bequaert, whose departure was postponed, sailed from New York on February 1, 1929. Work was begun at Chichén Itzá in on the day of arrival, February 8, although it was some days later before the portable laboratory was completely set up and fully equipped. The object of the Expedition was to make preliminary medical survey of Yucatán. With this purpose in view, two centers of

population, Dzitás and Chan Kom, were selected for special study. Dzitás exemplified the small town of mixed population having railway communications with the outer world, and Chan Kom typified the large, isolated village of practically pure Maya stock. In both places free clinics were held which made it possible, not only to examine a large proportion of the entire population of these localities, but also to supply the laboratory with quantities of material.

The physical examinations made in the clinics showed the development of the individual, his state of nutrition and the presence or absence of characteristic physical signs of diseases. The laboratory studies included estimates of hemoglobin, typing of blood specimens, Kahn and cholesterol reactions which have a significance like that of the Wasserman test, examinations of blood smears for malaria, Schick testing to determine susceptibility to diphtheria, examination of feces for protozoön or helminthic parasites, such as the amoeba of dysentery and the hookworm, culturing the feces for pathogenic bacteria, and bacteriological

testing of water supplies. Local epidemiological data were obtained by abstracting the records of births and deaths in Dzitás, and by house-to-house visiting and census taking in Dzitás and in Chan Kom.

Meanwhile, numbers of patients were examined and treated almost every day in the laboratory at Chichén Itzá and visits were made to various Indian villages. Conditions in them were found to be similar to those in Chan Kom.

After Dr. Sandground and Dr. Goodner had completed their work and returned home, the laboratory was virtually closed. I then made a visit to Uxmal, where malaria has been prevalent in the past. Subsequently, I undertook two trips into the forests of the Territory of Quintana Roo to compare conditions there with those in Yucatán and to learn what I could about the prevalence and distribution of an interesting ulcerative disease known locally as "chiclero ulcer" or *pique de mosca*. I had previously seen a few examples of this disease in Yucatán but they had been contracted in Quintana Roo.

The first journey was from Tizimín to the Colonia Santa Maria, about 80 to 90 miles [128.8–144.8 km] distant by road and trail, and the second was to Xyatil and Xpichil which lie about 95 miles [152.9 km] south-east of Peto. My party on these trips included Mr. Bennett and Sr. Felipe Castillo of Dzitás who served as interpreter. Clinics held at the Colonia for five days gave opportunity to examine a considerable number of Mexicans. Through the good offices of Srs. Cué Hermanos our party was provided with mules for the journey in both directions and was housed and fed at the "Colonia" without charge. The trip from Peto was very kindly arranged for me by Sr. de la Torre of the Mexican Exploitation Company and by Mr. Joseph F. Rehani of Mérida. The object was to visit the Indians at Xyatil and Xpichil who live under conditions differing from those at Chan Kom and who are even more isolated.

Dr. Bequaert, who was to collect biting insects and plants, postponed his coming until after the rains had begun because of the scarcity of insects and of flowers in the dry season. He reached Mérida on May 29 and proceeded the next day to Chichén Itzá. Subsequently, he spent a week at Chan Kom and, later, he obtained important information from Dr. Gaumer at Izamal. I sailed for home on June 24 and Dr. Bequaert followed on July 8.

The work of the Expedition has provided much information about the prevalence and distribution of disease in Yucatán. This information relates not only to bacteriological and parasitic diseases but to maladies of nutrition as well. There is also a large quantity of statistical data upon infectious diseases in the districts of Mérida, Progreso, Ticul, Valladolid and Peto, which was laboriously copied from unpublished offi-

cial sources, and a quantity of meteorological data, based upon official observations over a period of five years at Mérida. Dr. Sandground's work in helminthology extended beyond man to the lower animals, from which a number of most valuable specimens were obtained.

Collections of bacteriological, helminthological, pathological, entomological and botanical material were brought back by the Expedition to be worked up in the home laboratories. Samples of water and of soil were also secured. Dr. Bequaert and Dr. Sandground each obtained a few zoological specimens.

It will require a good deal of time to study all this material and to prepare a report upon the work of the expedition as a whole.

Mr. J. O. Kilmartin of the Chichén Itzá Project kindly prepared maps of Dzitás and of Chan Kom to be used in the report.

The Expedition not only carried out its program, but extended its activities over a somewhat wider field than was originally contemplated. This success is attributable to various favorable factors and especially the enthusiastic work of my associates, the friendly spirit of both Yucatecans and Indians, and, lastly, but not least, to the helpful cooperation of Dr. Morley and his staff at the hacienda in Chichén Itzá.

10.2.

KATHERYN MACKAY

Report on the Chichén Itzá Clinic

YB 28:315–316, 1929

The Chichén Itzá Clinic was open from January 4 to July 10 during the 1929 field season. Within a few days after its opening the Maya began to flock into Chichén Itzá from the surrounding country, whole families at a time. The influenza epidemic had just reached Yucatán and the Indian population was very generally affected.

Owing to the limited space available for the clinic, a single room where only three bed-patients could be accommodated at one time, only the most serious cases could be given continuous attention and treatment. At the height of the epidemic, an outlying thatched hut was pressed into service as a temporary though inadequate hospital. In these places the worst cases were handled; the others were given medicines with instructions how to take them, and sent home to treat them-

selves. A number of villages sent runners to Chichén Itzá for medicines, which were distributed, free of charge, until the supply was exhausted.

The epidemic was not particularly malignant, out of nearly 300 cases treated, only 8.5 percent had bronchial pneumonia, and of these only one died. The pneumonia cases were cared for as bed patients at the Clinic.

The Clinic drew patients from a radius of about 50 miles [80.5 km], many Indians walking long distances for treatment, mothers with babies in their arms, small children, even old men and women.

A total of 624 cases were treated during the season as shown in the following table. Most of these were cared for in the central Clinic at Chichén, but in addition outside clinics were held in the neighboring villages of Pisté, Xochenpich, Dzitás, Yulá, Nictéhá, Chan Kom and Kaúa.

The foregoing table requires little comment. In view of the epidemic, proportions of influenza this season it is not surprising to find that nearly half of the cases treated (47 percent) were for this disease alone. Dysentery and colitis come next with a total of 20 percent. Diseases of malnutrition such as pellagra and scurvy rank third with a total of 12.6 percent, and ophthalmia is fourth, 5.5 percent of the cases suffering from eye infections.

Table 10.2.1. Chichén Itzá Clinic Report, January 4 to July 10, 1929.

<i>Diseases</i>	<i>Children N Cases</i>	<i>Adults N Cases</i>
Influenza	105	165
Influenza complicated with pneumonia	15	10
Dysentery and colitis	75	50
Ascarus	10	5
Whooping cough	10	
Malaria (active)		10
Scurvy	4	
Pellagra		75
Ophthalmia	25	10
Skin Infections	25	
Accidents		30
Total	269	355

The very few cases of malaria treated is probably due to two factors: 1. There is very little malaria around Chichén Itzá itself, most of the cases being brought in from the outside, and 2. The clinic was open only during the dry season. A report of the same number of cases drawn from the same region for the last half year-July to January, that is, during the rainy season would undoubtedly show a much higher percentage of malaria.

Finally, it should be noted that practically 100 percent of the population, both children and adults, show ascarus infection, although very few are clinical cases, less than 2.5 percent during the 1929 season.

10.3.

GEORGE C. SHATTUCK
Medical Survey of Yucatán

YB 30:119-122, 1931

During the period under review, no field investigations were in progress, the medical party having returned from Yucatán in the spring of 1930. Since that time attention has been devoted to preparation of the report upon the work of the two preceding seasons. This is now ready for the press. It therefore seems appropriate to summarize the information gained to date, to formulate the outstanding problems which have emerged, and to lay plans for the future.

The object of the 1929 expedition was to make a preliminary medical survey of Yucatán. With this purpose in view two centers of population, Dzitás and Chan Kom, were selected for special study. Dzitás exemplified the small town of mixed population having railway communications with the outer world, and Chan Kom typified the large, isolated village of practically Maya stock. In both places, free clinics were held which made it possible, not only to examine a large proportion of the entire population of these localities, but also to supply the laboratory with quantities of material.

The physical examinations made in the clinics showed the development of the individual, his state of nutrition and the presence or absence of characteristic physical signs of diseases. The laboratory studies included estimates of hemoglobin, typing of blood specimens, Kahn and cholesterol reactions which have a significance like that of the Wassermann test, examinations of blood smears for malaria, Schick testing to determine susceptibility to diphtheria, examination of feces for protozoon or helminthic parasites, such as the amoeba of dysentery and the hookworm, culturing the feces for pathogenic bacteria, and bacteriological testing of water supplies. Local epidemiological data were obtained by abstracting the record of births and deaths in Dzitás, and by house-to-house visiting and census taking in Dzitás and in Chan Kom. Meanwhile, numbers of patients were examined and treated almost every day in the laboratory at Chichén Itzá, and visits were made to various Indian villages. Conditions in them were found to be similar to those in Chan Kom. During the 1930 season the principal objectives of study were the basal metabolism of Maya Indians, their blood pressures and their blood pictures with special reference to anemia. This work was done at Chichén Itzá. In Valladolid, the relative prevalence of syphilis among Maya Indians and Yucatecans was

investigated. Data on blood pressure, anemia, malaria and other diseases were likewise obtained.

The work of the expedition has provided much information about the prevalence and distribution of disease in Yucatán. This information relates not only to bacteriological and parasitic diseases but to maladies of nutrition as well. There is also a large quantity of statistical data upon infectious diseases in the districts of Mérida, Progreso, Ticul, Valladolid, and Peto, which was laboriously copied from unpublished official sources, and a quantity of meteorological data, based upon official observations over a period of five years in Mérida and also in Valladolid.

Our observations make it clear that dysentery and similar infectious diseases of the intestinal tract are responsible for about one-third of all the deaths in the State of Yucatán. Two groups of disease compete for second place: the malaras and acute respiratory troubles. The Maya Indians appear to suffer very little from syphilis; the significance of this phenomenon is not yet understood.

There are many medical problems in Yucatán which are worthy of further study.

1. The relative prevalence of the three kinds of malaria and their distribution in the peninsula is practically unknown.
2. The relative prevalence of amoebic dysentery, its distribution, and its significance as a cause of sickness or of death is a matter of conjecture. Further study of the bacterial dysenteries of Yucatán would yield very interesting results.
3. More information is needed about the prevalence of syphilis and of other venereal diseases and, particularly, as to the amount of damage actually caused by syphilis in Yucatecan communities. Related questions of the greatest scientific interest and of worldwide importance relate to the immunology of syphilis as it appears in various races in Yucatán, and among the Maya in particular.
4. The status of trachoma, a disease which might produce an important health problem in the future, should be known; and a satisfactory means diagnosis, as well as the cause and means of prevention of folliculosis the conjunctiva, should be determined.
5. It is of serious concern to those who engage in the gathering of chicle in the forests of Campeche or in those of Quintana Roo that means should be found by which they may protect themselves from "chiclero ulcer." Typical cases of this disease are believed to be caused by infection with *Leishmania*.

Further study of the prevalence and distribution of amoebic dysentery and of malaria in Yucatán will, probably, be undertaken in the near future; during the early months of 1931 additional information was obtained about folliculosis in Yucatán; and it is hoped

that investigations of syphilis and of other diseases among the Maya of Guatemala may be undertaken next year.

Although much more study is required to enable man to improve and to extend his control of infectious diseases in the tropics, and, to improve treatment for these diseases, so much has been learned already that a great deal can now be done wherever funds are available for the purpose.

But there is a vast new field of work which has scarcely been touched thus far and which will inevitably be recognized more and more generally as of paramount importance. I refer, firstly to the physiological mechanism of adaptation to life in the tropics, not only as it exists among indigenous races, but also as it affects individuals belonging to races which have developed in a temperate climate and who have gone to live in the tropics temporarily or permanently; and, secondly, to the discovery and application of means of mitigating the ill effects of tropical environment.

It seem that this great group of questions might be attacked from two sides; namely, by physiologists on the one hand and by climatologists on the other.

The work of the physiologist is greatly handicapped in the tropics by the presence of disturbing factors which may be impossible to control and which may, otherwise, be difficult or impossible to evaluate. Normal standards must be based upon the study of normal individuals, but malaria, hookworm disease, faulty diet, and unhygienic habits, such as the excessive consumption of alcohol, or a combination of these factors very frequently complicate the picture.

Yucatán has two special advantages for such studies: firstly, hookworm disease is practically non-existent there; and, secondly, malaria is far less common and is, generally, less severe than in other parts of the tropics. Unhygienic habits and doubt as to the adequacy of diet must be reckoned with in Yucatán, however, as in most other tropical countries.

The true nature and cause of "sun-stroke," "heat exhaustion" and "airiasis" requires further study, not only in various kinds of tropical environment but also in the hot summer climates of the temperate zone. Why, for example, is the sun regarded with so much dread in India and in Africa whereas in the tropics of the Western Hemisphere and in the Philippine Islands the sun seems seldom to have serious effects? Is this mere superstition or would close study of solar radiation and of other climatic factors in these various localities show differences which might prove equate causes for the prevailing beliefs?

The industrial hygienists have already made observations upon the effects of heat, humidity and dust content of the atmosphere and upon human beings who have been subjected for short periods to these

various influences under carefully controllable conditions, but what of the heat or humidity or both to which residents of the tropics are subjected for months, years, or throughout life?

Solar radiation has been analyzed quantitatively at Davos in Switzerland and elsewhere and new instruments have been devised for the purpose. But should not solar radiation be studied in different parts of the tropics by similar means? Has it been shown beyond doubt that invisible solar rays other than the ultra-violet are harmless? Have cosmic rays any significance for health? What of atmospheric ionization and atmospheric electricity, not only in the tropics but also in the temperate zone?

It is proverbially easy to ask questions and difficult to answer them, but are not most of these questions pertinent to health? Is it not essential that much more should be known about climate and acclimatization in order that the tropics may be fully developed in the future as sources of food and of other materials, which will be more and more urgently needed by future generations of man?

The problems here suggested are vast. Programs for attacking them will require not only the consideration of physicians, of physiologists, and of meteorologists, but specialists in certain branches of biology, of chemistry, and of physics will be able to make essential contributions also.

The expense of initiating such work will depend upon the breadth of the programs undertaken. Strong financial backing over a period of many years will be needed before the results are likely to provide the information necessary for the basis of a new hygiene of the tropics. Man must learn to minimize the ill effects of tropical climates which are now universally recognized to operate against the efficiency of races from the temperate zones when they undertake to live or to reproduce their kind in tropical environment.

10.4.

MORRIS STEGGERDA

Physical Anthropology in Yucatán

YB 30:124-125, 1931

One branch of physical anthropology studies living man and attempts to apply a yardstick to as many of his characteristics as possible. For the external fea-

tures of the human body, this yardstick is called an anthropometer for the brain, mental tests are used as a measuring tool; and for the physiology of the human being various chemical reactions serve as a basis for measurement. Human heredity may well be considered as a branch of physical anthropology. In heredity, emphasis is laid on likenesses or similar characteristics between offspring and their parents. These likenesses must be measured and tested in a similar manner to that employed by the physical anthropologist. Naturally race crossing offers a profitable field for the study of human heredity, since the more widely separated the parent stocks, the more obvious are characters recognized in the offspring. In Yucatán the Spaniards and the Maya Indians have interbred since the Conquest. If this process were still going on, it would be possible to get "F1" hybrids which from the standpoint of human heredity are essential.

By "F1" hybrids we mean hybrids of the first generation. After a general survey of four months in the State of Yucatán it is the opinion of the author that such crosses no longer occur, and the hope that such data can be secured in abundance will have to be abandoned. The survey, however, presented other problems of equal value. These problems are discussed later.

The purpose of the past season's work, aside from obtaining the survey, called for a study of the relatively pure Maya Indians, from three angles, namely, physical, psychological and physiological. The work progressed unusually well, due to the facilities offered to us and the contacts made for us by the staff of the Division of Historical Research of Carnegie Institution of Washington, at Chichén Itzá. The author was accompanied his wife, who acted as a recorder, and by a native Maya man who acted as interpreter.

At present the field records are being analyzed at Cold Spring Harbor. In this report only the numerical field results will be mentioned, along with some more general observations.

About 75 physical measurements were made upon each of 50 adult males, 50 adult females, and 175 children. These measurements include stature, length of arms and legs, body segments, measurements of head and face, palm, finger and sole prints, examination of teeth, description of hair and eyes, and others.

These measurements are being analyzed statistically and will in time be published. Those on the adults may well supplement the more extensive work, done in 1927 by Dr. G. D. Williams of Harvard, which will soon be published. The measurements of the children, it is hoped, will form only a beginning of a larger program of the study of growth of Maya Indian children. Such work is now being done for white children. From examination of the 200 palm prints which were gathered, there appears a distinct racial difference in the

pattern among the Yucatecan Maya, when compared with the white and black races already studied.

Psychological tests were selected with a great deal of care, so as to eliminate such natural barriers as difference in language, and also speed, our white children are taught from infancy that speed is a factor in life. The tests were given individually and no group tests were attempted. The tests include: 1. Knox cube imitation test (*Journal of the American Medical Association*, 1914, pp. 741-747); 2. Stringing of beads (Eugenics Research Association, 1931); 3. Hollow square (Harvard Monographs in Education Series I, no. 4, 1931); 4. Ferguson Form Board (*Journal of Experimental Psychology*, 1920); 5. Sequin form board (Goddard 1912); 6. String tests (Columbia Contribution to Education, 136); and, 7. Nonsense syllables (Eugenics Research Association, 1931).

The above tests were applied to 40 adult males, 25 adult women and to 35 children. In general it may be said that the males do better than the females. This is due quite likely, not to superior intelligence, but to the lack of forwardness on the part of Maya females who are exceedingly docile and reserved. The chief difficulty in giving psychological tests in the field is the fact that one cannot control the surroundings of the individual taking them. There are no doors to close and, if there were, it would not be expedient. It was apparent from the manner in which the natives took the Sequin Form Board test that they are instinctively honest, and not given to crafty trickery. It is the opinion of the author that advancement in mental testing of foreign races will be slow and difficult.

Physiological work was done in connection with the Nutrition Laboratory of the Carnegie Institution. Basal metabolism records were made on 31 Maya men, each man being run three periods per day for three successive days. In obtaining the basal metabolism of an individual, one must determine among other things the amount of oxygen he consumes in a given unit. A portable field instrument was designed to determine this. Other areas noted were pulse rate, respiration, age, height, weight, temperature, barometric pressure, etc. The results of this aspect of the work are a confirmation and an establishment of the fact that Maya men have a higher metabolic rate than the standard determined from white men in this country. They were found to be 7 percent higher than white men. This is probably a significant racial difference.

In performing the above outlined anthropological studies, care was taken to select individuals from relatively large families; thus the data can later be used in making family studies as well as merely averages for the physical anthropologist. Pedigrees for the families of Pisté and Chan Kom are now made and many interesting facts will be learned.

Naturally one questions the genetic purity of the race studied. It is the author's opinion that Maya Indians can be found in Yucatán who may be considered from 90 to 100 percent pure descendants of the original ancient Mayas. Mestizos can be found who would represent approximately 50 percent Indian and 50 percent Spanish blood. These, however, are not "F1" hybrids. It is true also that there are relatively pure whites to be found. There is, indeed, a large amount of anthropological work to be done on these three groups. Since the peninsula of Yucatán is geographically restricted, it forms an admirably compact and definite field; and since the facilities offered by the Division of Historical Research are so excellent, it seems most desirable that further investigations may be carried on there by the Department of Genetics. It is also hoped that similar studies may separately be made of other subdivisions of the Maya people, as for example, those found in the highlands of Guatemala.

10.5.

GEORGE C. SHATTUCK

Medical Research in Yucatán and Guatemala

YB 31:107-111, 1932

The Third Yucatán Medical Expedition: George M. Saunders, M.D., Clinician, in charge; Frank H. Connell, Ph.D., Protozoologist; Byron L. Bennett, Laboratory Technician, was in the field from June 23 to September 23, 1931. The primary purpose of the expedition was to collect information upon the various forms of malaria and amoebic dysentery.¹ The investigations of 1929 and 1930 had thrown much light upon the prevalence and distribution of disease in general in the State of Yucatán, but had provided insufficient data of this kind about the above two diseases, which are of special importance as causes of morbidity and of mortality in many tropical countries. Statistical data indicated that both malaria and amoebic dysentery are far more prevalent in Yucatán in the summer than in the winter and, consequently, it became clear that observations relating to them could best be conducted in the summer. Dr. Saunders' expedition not only undertook to do this but also to add to the series of blood-pressure measurements, a considerable number of which had been made by the other expeditions, and which indicated that excessively high blood-pressure is uncommon in Yucatán and, particularly so among the Maya,

their average blood-pressure being apparently distinctly less than that of the United States or Europe.

The nature of the investigation required the making of observations at a number of different places scattered over the State. A minimum of eight localities was selected, it being left to Dr. Saunders to cover others if time should permit. By energetic and rapid work his expedition succeeded in holding a series of clinics and in making the needed observations in 11 towns or villages; Mérida, Progreso, Chichén Itzá and vicinity, Valladolid, Temax and Buctzotz, Muna, Peto, Izamal, Dzilam Puerto and Telchac. On the average, about a week was spent in each place. This expedition was beholden to the Governor of Yucatán, Sr. Bartolomeo García Correa, and to numerous town officials, and to Sr. Fernando Barbachano P. for kind cooperation in furthering its objects.

The findings of Saunders and Connell indicate that infestation with amoeba of the type which cause dysentery is extremely common in Yucatán and it seems highly probable that this organism is in fact a serious menace there not only to health but also to life. The presence of the three types of malaria in Yucatán was demonstrated by finding the three varieties of malarial organisms, but comparatively few of the blood examinations made showed the presence of plasmodia. It appears, therefore, that although malaria has undoubtedly prevailed to a serious degree in parts of the State of Yucatán at various times, the disease was not very common in that State during the summer of 1931. Malaria in Yucatán is by no means the scourge that it is in most tropical countries. Undoubtedly, one reason for this is the comparative scarcity of surface water in which the mosquito vector might breed. The blood-pressure observations, in general, confirmed and strengthened those of the earlier expeditions.

The data obtained by Dr. Saunders' expedition form Part III of the full report of the three medical expeditions to Yucatán, now in press for publication by Carnegie Institution under the title of *The Peninsula of Yucatán*.

The First Guatemala Medical Expedition: George C. Shattuck, Clinician in charge; Wilhelm Curth, M.D., Dermatologist; Carlos Sánchez, A.B., Secretary and Interpreter; Byron L. Bennett, Laboratory Technician, was in the field from January 30 to March 22, 1932. Its objectives were: 1. To gain a general knowledge of the diseases prevalent in the highlands of Guatemala; 2. To compare the observed conditions with disease conditions in the low Yucatán peninsula with special reference to the Indian population, their mode of life, and other factors which might have a bearing on their health; 3. To obtain the fullest possible data upon the frequency and severity of syphilis among the Indians, as well as among the Ladinos (mixed bloods) of this

region; 4. To collect available statistical data upon mortality and morbidity in Guatemala as a whole; 5. To gather available climatological data.

Comparatively little has been published of a specific or even of a general nature about disease in Guatemala, so that there was needed a good deal of first-hand clinical information, as well as general information of the sort to be had by interviewing informed people on the ground. It was thought that differences in the prevalence of disease might be correlated with mode of life and climate and that certain inherent weaknesses or resistances of the Indians might be thrown into relief by comparing the health status of the Indians in the Guatemala highlands with that of the Maya of the lowlands of Yucatán.

It was not believed so important to study disease on the coastal plain and in the highlands because on the coastal plain the climate and environment is essentially tropical, and there was every reason to expect to find there the usual diseases of the American tropics. Moreover, the prevalence of malaria and dysentery there was well known through the hospital work of the United Fruit Co. and the Rockefeller Foundation had made special studies of the distribution of hookworm disease and of malaria in Guatemala.

A problem of far-reaching importance had been envisaged in Yucatán where it appeared to be a fact that the Maya have an extraordinary resistance to injury and perhaps also to infection by the virus of syphilis. This suggests that syphilis is an old disease among the Maya, and that, in consequence, they have acquired a higher degree of immunity against it than has been demonstrated in any other race. This hypothesis has an important bearing on the history of syphilis by implying that the disease existed in Central America long before the Conquest, that it originated there, and that it was first brought to Europe from the New World by the sailors of Columbus. Belief in an American origin of syphilis has long been held by many, but opponents still insist that it is much older in China than in Europe and that it came to Europe by way of the East. These considerations, and the doubts cast by expert serologists upon the above interpretation of our findings in Yucatán, caused the inclusion in the Guatemala Expedition of Dr. Curth, a specialist in skin diseases and syphilis.

After consultation with Dr. Kidder and others, plans were made to study the Indian and Ladino inhabitants of the villages about Lake Atitlán. Reconnaissance of the region led to choice of Panajachel as a base, and the laboratory was set up there in the schoolhouse. Introductions to officials had been most kindly furnished by General Ubico, President of the Republic, so that their cooperation was readily secured. It remained, however, to gain the confidence of the Indians

in order that they would come to our clinics for examination and treatment and would willingly permit us to take samples of blood to be subjected to serological examination for syphilis. Mr. Carlos Sánchez, who was sympathetic to the Indians and who knew personally some of those living about the lake, not only served as interpreter, but was of inestimable service in winning for us the good will of all classes of people of the region, with the result that we had an adequate supply of patients and no time was lost at Atitlán. At Chichicastenango, where a few clinics were held, Padre Rossbach helped us in the same way. The work went forward so rapidly that there was time to accept the invitation of Mr. Gordon Smith to continue our work on his coffee plantation. Although he had anticipated no difficulty, the Indians proved refractory and little was accomplished in the week spent there.

As result of the investigation, dysentery was found to be by no means as prevalent in the highlands of Guatemala as in Yucatán. Malaria of importance is found only in a few villages on the shores of Lake Atitlán. Hookworm disease is scarce, and when seen has always, or nearly always, been contracted during periods of work upon the plantations on the coast. In general diseases in the highlands are those of the temperate zone rather than of the tropics. Tuberculosis, rheumatic fever, cancer, and the degenerative diseases which affect the arteries, the heart and the kidneys are notably unusual, outside the large towns and cities. This is true not only in Guatemala but also in Yucatán.

As in Yucatán, so also in Guatemala, those of pure Indian stock, and to a less degree those having a large admixture of Indian blood, show an extraordinary resistance to damage of the virus of syphilis. Careful physical examination by Dr. Curth and 500 serological tests (300 on Indians and 200 on Ladinos) support this statement.

In the course of our work two other conditions were noted; namely, the prevalence of goiter and the high cost of quinine, which puts this drug beyond the reach of most of those who suffer from malaria. The President of the Republic, other high officials of the Government, and representatives of the United Fruit Co. all became interested in the suggestion that quinine for home consumption might be produced at minimum cost in Guatemala to the advantage of all concerned; and the Director General of Health accepted with alacrity an offer to collect and send him recent literature upon methods of preventing goiter.

NUTRITIONAL AND ANTHROPOMETRIC STUDIES

By far the most important of the manifold practical problems of human existence is that of filling the stom-

ach. Men must be fed before any other activity can be undertaken. The quality and quantity of their food determines their health and vigor; the ease or difficulty of its attainment regulates the amount of effort they may put into activities beyond and above the mere business of keeping alive. Food supply and physical environment interlock to produce the most cogent conditioning factors of any people's career. No anthropological or historical investigation can therefore strike very deep without taking them both seriously into account.

In research upon the Maya, questions of food arise at every turn. Interpretation of the findings of archaeology hinges, for example, very largely upon understanding of how it could have been possible for this race to have wrested a bare subsistence from a region at once so thin-soiled and so densely jungled, to say nothing of having garnered sufficient surpluses to have enabled them to devote obviously large amounts of their time to such superfluities as the building, without the aid of metal tools, the wheel, or beasts of burden, the huge religious structures with which many parts of their former range are literally crowded. All calculations of ancient population must be based upon estimates of the country's crop capacity; all judgment of the physical condition of the modern Maya must rest upon knowledge of the nature of their food.

An illustration of the last statement is provided by the inquiry into the basal metabolism of the Maya. Dr. Williams' original determinations, made at the instance of Dr. Benedict of the Institution's Nutrition Laboratory, showed the Maya to be paradoxical in possessing a very high metabolic rate combined with an abnormally low pulse. Dr. Shattuck's check confirmed Williams' and Dr. Steggerda's most carefully controlled recheck placed the matter beyond dispute. This extremely unusual condition may be, it is thought, innate, in which case it becomes a most useful criterion of race. It may be caused by action of the cold Yucatecan nights upon thinly-clad, blanketless hammock-sleepers. If so, it may have important bearings upon study of the functioning of the ductless glands. But, in either case, the problem can not be settled until we know exactly what the modern Maya eat to produce the bodily activities expressed by the basal metabolism measurements.

So both archaeology and physiology need information regarding food. And widely separated as are the problems which they seek to solve, they both, together with the many other inquiries which are also brought to grips with questions of nutrition, come down, in the last analysis, to insistent demand for a single piece of primary data: the man-per-day ration of the Maya Indian.

This seems a simple matter. But surprisingly enough, one discovers that the best we can offer is the

vague statement that the Maya live largely on corn in the form of tortillas, eked out by a certain amount of beans and other vegetables and a little meat. The exact amounts consumed, the quality of the various comestibles, the nature of their preparation; of all such things we are completely ignorant.

A start toward remedying this unfortunate situation was made during the past winter at Chichén Itzá by Dr. Steggerda, who, after learning the necessary technique in Dr. Benedict's laboratory, collected and preserved 65 food samples. He also made exact record of everything eaten by four Maya men for three successive days. The material has been sent to the Nutrition Laboratory for analysis. Many further observations will, of course, have to be made in different parts of the region, during all seasons, and upon people of various ages, economic positions and occupations.

While we are still upon the subject of food, it may be permissible, before taking up Dr. Steggerda's other work in Yucatán, to mention a second aspect of the matter which has not yet been given adequate attention. Before consuming his food, man must get it. The Maya staple is, and evidently for a long time has been, corn. Therefore of equal importance with the man-per-day ration is the corollary problem of the bushel-per-acre capacity of the land. This, again, is unknown, although several years ago Mr. O. F. Cook of the United States Department of Agriculture made, at Dr. Morley's suggestion, a beginning of such a study. It is imperative that it be continued. We must go into the whole agronomic situation, highland and lowland, in the greatest possible detail, learning from the historian all we can of farming practice at the time of the Conquest, from the ethnologist how the modern Indians sow and harvest, from the geologist and geographer the nature and extent of cultivable terrain, from the soil chemist its potentialities.

To return to Dr. Steggerda. This gentleman's collaboration in the survey is made possible by the Institution's Department of Genetics. His primary interest is in the genetic aspects of physical anthropology. He has carried on the anthropometric work begun by Dr. Williams and has added thereto a study of Maya growth, selecting, for continuing observation, with the expectation of following them year-by-year through adolescence to adult life, the children of Pisté and Chan Kom, Indian villages in the neighborhood of Chichén Itzá. For comparative purposes he is about to start a parallel study of Navajo Indian children in Arizona. He is also collecting data regarding certain large family groups. In 1932 Dr. Steggerda was in the field during March and April. Dr. Davenport, Director of the Department of Genetics, came to Yucatán with Dr. Steggerda to make acquaintance with the field and to gauge its possibilities for genetic research. It is one

of the greatest advantages of the Chichén Itzá headquarters that it permits members of the resident, staff to have contact with other scientists and to see their own problems from fresh points of view.

NOTES

1. The health survey of the Maya area is a joint undertaking of the Department of Tropical Medicine of the School of Public Health of Harvard University and Carnegie Institution of Washington. For reports upon the work of previous years, see [Chapters 10.1 and 10.3].

10.6.

MORRIS STEGGERDA

Anthropometric and Other Studies

YB 32:106-107, 1933

With Mrs. Steggerda acting as recorder, I began this season's work at Chichén Itzá on January 31. This was our third year of work in Yucatán on the problem of growth in different racial groups. In the Maya growing series, there are 92 boys and 78 girls from the villages of Pisté, Chan Kom and Xochenpich. These children have now been measured for three successive years and it is planned to measure them annually until all have finally matured. Similar series of white and Negro children have been measured, with which these will be compared.

It has been our purpose from the beginning to analyze genetically as many families as possible in the towns in which we worked. From the first year we have plotted pedigrees of the families, showing their relationship and the number of children per fraternity, also stillbirths and miscarriages. We have determined the relationship in detail of every family in Pisté several in Chan Kom and some in Xochenpich. At present we have 45 pedigrees, representing some 500 or more individuals; of the number fully two-thirds have been measured in detail, some of the children several times. Each season we measure additional members of the families, record any who have died, married, or moved away, and other like notes.

In order that the family study may be as detailed as possible and also possess sociological interest, we had made, with the cooperation of Dr. Morley, a map of Pisté showing all streets and houses. We then made a canvass of the town, and thus determined just who

lived in each house and the purpose of the house (dwelling, storage, kitchen, laundry, apiary, etc.). In addition, we have taken for permanent record typical photographs of streets, houses and yards. Furthermore, we made this season a complete census of the town. This includes the number of adult males and females and children both living and dead for each. fraternity, as well as the size of each man's milpa (corn field), during the last two years, number of horses, cows, pigs, chickens, beehives, dogs and other animals.

Realizing the importance of the agronomic problem for all Maya studies, I wished to gather as accurate data as possible regarding soil deterioration under cultivation. We know in general that the Indians abandon their milpa after two successive years, and that the corn yield is about 50 percent less the second year than it is the first. We accordingly selected a *mecate* (approximately 400 square yards [334.5 square m]) of typical land, bounded it with stones and took a sample of its soil for analysis. It is hoped that each year corn may be grown on this *mecate* and its soil annually analyzed in order to determine quantitatively the amount of deterioration and the percentage of loss in corn each year.

In addition to the above, there was made a study of the stature of the human figures carved upon the columns of the Temple of the Warriors, which indicated that while the sculptures are some shorter than living Maya, the range of distribution for stature is the same. This perhaps lends color to the theory that the figures are actual portraits of individuals. Another activity was the gathering of saliva samples from Pisté men for Dr. Weston A. Price of Cleveland, who is conducting researches upon the causes underlying dental caries. Mouth-casts were also made for Dr. Price.

Leaving Yucatán on March 4, we undertook a reconnaissance trip in the highlands of Guatemala and in the Mexican state of Chiapas, with a view of determining the possibilities of those regions for an extension of the anthropometric and genetic studies already under way in Yucatán.

We were able to measure several adults, making approximately 75 observations on each subject. A few of the essential dimensions are given below to indicate their general characteristics [Table 10.6.1].

From these figures it will be seen that the two groups are of about the same stature and that the Yucatán Maya have shorter and broader heads and are thus more brachycephalic than the highlanders. The Yucatecans also have broader faces.

We were impressed by the high percentage of goiter in the highlands and by the absence of baldness which is so common among Yucatán Maya women. The highland Maya are also more independent and seem more artistic than those of Yucatán. We have

Table 10.6.1. Anthropomorphic Measurements of Highland and Lowland Maya.

	75 Quichés and Mams Guatemala	77 Yucatán Maya
Stature	153.2	155.1
Head Length	183.7	180.4
Head Breadth	143.9	153.7
Cephalic Index	78.4	85.0
Bizygomatic Width	137	143
Bigonial Breadth	107	106

made some excellent contacts in Guatemala. We believe that the metabolism of these people should definitely be determined and also that further anthropometrical work should be done, so that a closer comparison can be made with the Maya of Yucatán.

10.7.

MORRIS STEGGERDA

Studies in Physical Anthropology and Human Geography

YB 33:98–100, 1934

As in recent years, the Department of Genetics has cooperated with Division of Historical Research by sending Dr. Morris Steggerda to Yucatán to carry on studies in physical anthropology and upon population.

One of Dr. Steggerda's major problems concerns the comparative growth of children of different racial groups. Maya children of the village of Pisté near Chichén Itzá, constitute one of these groups, Navajo, Dutch white, and Negro children constituting the others. One hundred and 70 Maya children have now been measured in detail for four successive seasons. Many of the young girls measured first in 1931 are already married and some have children, and likewise several of the boys have now taken their places among the working men of Pisté. Growth curves are being made of each of these 170 children, considering not only height, weight, span, sitting height, and others usually considered, but also the development of the teeth and other bodily proportions. We now have standards for the Dutch whites, Navajos and Negros, and in another year in Yucatán we hope to measure a number of Maya children who will form the standard with which we can compare our individual growth curves.

Dr. Steggerda has likewise studied the finger prints of a series of 127 Maya Indians of Yucatán. The prints have been treated in the usual manner, by considering pattern type, pattern size (quantitative value) and pattern form. In this series 33 percent were whorls, which is slightly less than is found in other collections of North American Indians, but considerably higher than among Dutch whites, who show an incidence of 20 percent for whorls. Arches among the Maya had a frequency of 7.6 percent; this is higher than is generally found. The hypothesis that a greater frequency of whorls occurs among brachycephalic than among dolichocephalic peoples was tested with the Maya and Dutch material, and the conclusion was reached that no correlation exists between fingerprint traits and cephalic index.

For a number of years, Mrs. Steggerda has been interested in racial differences in palmar dermatoglyphics. It has been known that three of the main lines on a Negro palm generally fall in positions 7, 5 and 5, and that in whites these lines terminated most generally in positions 11, 9 and 7. It is of interest that 27 percent of the Maya fall in an intermediate position, namely 9,7,5, with 22 percent in the 7,5,5 group and 17 percent in the 11,9,7 class.

For purposes of genetic study, Dr. and Mrs. Steggerda have been plotting the family relationships of the Indians with whom they have been working in Yucatán. For the village of Pisté, which has been the seat of much of their investigation, they have accurately recorded all family relations. Thus, every person is accounted for on some pedigree. Each year the pedigrees brought up to date in the matter of births, deaths and marriages.

Thirty-four Pisté mothers, whose reproductive spans have been completed, produced 264 children, or an average of 7.8 children for each woman. The chances are that the rate is even higher, since not all dead children have been recorded. Of the 264 children, 90 are known to have died, which is approximately 34 percent. This figure is undoubtedly lower than the actual mortality rate. Family data of this sort, when fully tabulated, will permit computation of not only the average number of children for a large number of mothers, but also the average age of the mother at the birth of first child, which appears at present to be much younger than among white mothers. It will also be possible to determine the number of legal husbands and wives per individual, which is also higher than for whites.

In order to gather data bearing upon the problem of population shifts in Yucatán there was begun an accurate yearly study of other people of Pisté. It was learned from an elderly woman that when she first came to Pisté 50 years ago there were only six or eight families in town. Now there are more than 50.

Table 10.7.1. Population of Pisté, Yucatán, 1933 and 1934.

	1933	1934	Increase	Arrivals from Other Towns	Left Town
Adult males	85	101	16	14	4
Adult females	70	85	15	15	2
Boys	78	89	11	8	3
Girl	74	96	22	10	1
Total	304	371	64	47	10

From this table can be seen the results of migration and change. Fourteen adult males arrived from other towns, and four left, making an increase of 10. The difference between this figure and the total increase in men (16) is accounted for by the recruiting of six town boys into the adult group. The names and relationships of all these men are known and recorded, as well as those of the women and children. It is of interest to note in this connection that in 1933 there were 72 men subject to police duty as compared with 82 in 1934. In 1933 there were 13 men listed as officers, aged, sick and inactive as compared with 19 in 1934. In 1934 there were 68 fraternities (husband, wife and at least one child) in Pisté. Dr. Steggerda has also collected statistics upon births, deaths and marriages in Pisté; he has made a house-by-house census; and has listed and classified buildings and outbuildings. He has likewise collected statistics upon livestock of all types, upon food consumed, and upon soil deterioration. All these classes of information will be of the greatest value for the eventual synthesis of the human geography of Yucatán.

10.8.

S. T. CLARKE

Investigation of Chiclero Ulcer

YB 33:108-109, 1934

As a cooperative project of the Department of Tropical Medicine of the Harvard Medical School, the Chicle Development Company of New York, and Carnegie Institution of Washington, Mr. S. T. Clarke spent part of the summer of 1933 in the Department of the Petén, Guatemala, in an attempt to determine the method of transmission of "chiclero ulcer," a form of epidermal leishmaniasis particularly prevalent among persons who gather, in the jungle, the substance known as chicle, the basic ingredient of chewing gum. Mr. Clarke

reached his base at El Paso, a station of the Chicle Development Company, by boat via the Usumacinta and San Pedro Rivers. Work was carried on at El Paso and at camps in the forest where the chicleros were engaged in bleeding chicle.

"Chiclero ulcer" is a disease apparently always contracted by men actually at work in the jungle. Lesions occur on exposed parts of the body, most commonly on the ear, which in severe cases is eaten completely away. About 10 percent of all chicleros in the infested region are sooner or later attacked. The method of transmission of the causative agent is unknown. As "chiclero ulcer" is seemingly never contracted by one individual from another directly, it has been thought that contagion must be brought about by an insect vector. The objective of Mr. Clarke's journey was a preliminary study of the manifestations of leishmaniasis in the Petén and collection of the local insects which commonly bite man and animals and of which some one may be responsible for the spread of the disease.

Several cases of chiclero ulcer were examined, and statistics were gathered as to its incidence according to season, occupation, age and sex. It was found to occur only during the rainy season; and among adult males working in the chicle forest. It is evidently the result of exposure to conditions occurring only in the active pursuit of chicle gathering, for, as far as could be learned, it never appears in towns or even among the women and children, limited numbers of whom sometimes accompany the men as far as the forest camps.

Various insects have been suspected as carriers: especially sand-flies and the yellow fly (probably the hippoboscids, *Olfersinoe coriocea*), which lives or feeds under the wing of a large forest bird, the faisán (*Crax globicera*). The chicleros almost uniformly believe that the latter is to blame. Mr. Clarke's endeavor to identify the vector had negative results. He was unable, in spite of very careful search, to find any sand-flies in the region; nor could he discover hippoboscids upon the few faisans which he succeeded in shooting.

Furthermore, no faisán or other bird or animal collected showed any sign of lesions similar to those produced by leishmaniasis in man. Mr. Clarke believes, however, that an animal of some sort must act as reservoir for the disease and that the carrier is probably a natural parasite of this host which will also bite man when he lives or works in the same environment that is occupied by the host.

In addition to his study of "chiclero ulcer," Mr. Clarke gathered valuable data upon traveling conditions, and the social and economic life of the few inhabitants of this sparsely and seasonably populated section of the Petén. His notes upon these subjects have been added to the files of geographic and ethnological information at Division headquarters.

10.9.

MORRIS STEGGERDA

Physical Anthropology and Human Geography

YB 34:129-132, 1935

The Department of Genetics has again cooperated with the Division of Historical Research by making it possible for Dr. Steggerda to continue field work in Yucatán.

In his visits to the peninsula, Dr. Steggerda has been concerned primarily with the growth of children, this investigation forming part of his larger program in the comparative anthropometry of childhood and adolescence.

He has now carried the work at the villages near Chichén Itzá where he is able to make the necessary annual measurements in a relatively short time and is consequently free to devote a part of each field season to other somatological problems and to studies of the human ecology of the region. By so doing, Dr. Steggerda has contributed signally to the Division's program by undertaking researches in somatology, agronomy, nutrition and various other aspects of present-day native life, all of which are of great importance for the interpretation of Maya history, but which neither are archaeologist nor archivist is competent to prosecute.

On the physical side, Dr. Steggerda confirms the opinion of other observers that the Maya are among the shortest of all North, and Central American Indians. During the past year it was found that the Maya from the eastern part of Yucatán (Chichimila) are statistically equal in stature to those in the Chichén Itzá area. Their heights are 156.62 ± 0.42 cm for men 142.85 ± 0.46 c. for women, as compared with the Chichén males of 155.11 ± 0.40 cm and females of 142.72 ± 0.42 cm. It is of interest also to find that the Mam and Quiché males measured in Guatemala averaged 154.66 ± 0.47 cm. Dr. Steggerda believes that the natives of Chichimila possess somewhat more Spanish blood than those of the Chichén region, and that those from Chichén are in turn perhaps more mixed than the Quichés of Guatemala. This may account for the differences in stature for the three groups. Possible mingling with other native stocks, environmental conditions and food-supply must, however, all be considered as factors bearing on this problem. During the past five seasons a considerable portion of the state of Yucatán has been examined, with the result that the Indians of the Chichén Itzá area are thought to represent as pure a Maya type as can be found in northern Yucatán.

In 1935 there was also opportunity to measure four Maya from San Cruz de Bravo. In bodily proportions these Indians conform very closely to the Chichén Itzá type. In stature they were equal to the general average from northern Yucatán. Their cephalic index ranged slightly lower. Their teeth were excellent.

In collaboration with Mrs. Steggerda, a paper has been completed on palmar dermatoglyphics, with special reference to the Maya. The palm prints of the Maya are characterized as follows: 1. A high frequency of the 9.7.5 type of formula; 2. An unusually vertical general configuration of the palm, as indicated by the proximal terminations of Line A; 3. The frequent reduction of Line C to a rudimentary and more often a totally absent condition; 4. The occurrence of a single comparatively low axial triradius; 5. An unusually low incidence of the hypothenar pattern; 6. The low incidence of the second and third-interdigital patterns; and 7. The exceedingly high frequency of the thenar-first interdigital patterns. It is most significant that the Chinese studied by Wilder (1922) conform in every detail except the last to these characteristics. It is only in the low percentage of the thenar-first interdigital pattern that the Chinese, and Mongolians in general, differ significantly from the Maya and other American Indians.

With Dr. T. J. Hill, Professor of Clinical Oral Pathology of Western Reserve University, analysis has been undertaken of the tooth condition of the Maya Indians. Over 1,100 mouth examinations have been made. Of males whose permanent teeth have erupted, 19.6 percent have caries to some degree, as compared with 21.7 percent for females. This means that of the Indians of the Chichén Itzá area nearly 80 percent do not have caries in their permanent teeth. Considering the extent of caries in such persons as have tooth defects, it can be said that the males have on the average 2.8 cavities and the females 5.3. The conditions found in the deciduous teeth are also of interest; as compared with those of the whites they are remarkably free from caries. The percentages are higher in the deciduous than in the permanent teeth. For comparative material Dr. Steggerda has observations on more than two thousand young Navajos, of whom only 15 percent of the males and 21.7 percent of the females had carious permanent teeth. The Dutch white material, which will also serve for comparison, is not yet fully analyzed, but there is every reason to believe that it will not vary greatly from the usual carious condition found among whites, which is at least four times greater than that found in the above two Indian populations.

The investigation on the food of the Yucatecan Maya is approaching completion. It has been shown that their diet is very rich in carbohydrates and low in proteins. From weights of the foods consumed daily

by Maya laborers, it was learned that between 75 and 85 percent of their diet consists of maize products.

The vital statistics of the village of Pisté, in the immediate vicinity of Chichén Itzá, have been gathered over a period of several years. The following is a summary to date. In 1935 there were 415 inhabitants, of which 207 were males and 208 females. In this town, during the last 17 years, the birthrate averaged 60.1 per 1,000 and the death rate 31.7 per 1,000. Of all the children born in 109 families, 17.2 percent died under two years of age. The sex ratio of the children born was 108.5 males to 100 females. The average number of children per completed family was 6.7, and the interval between the births was 28 months. The average age of the women at the time marriage is about 15.7 years. However, this figure is not as accurate as it should be, since many of the recorded ages are not official. The average age of mothers at the birth of their first child, based on exact birthdays, is 18 years.

From the animal census taken in Pisté during the last three years a number of interesting facts have been learned. For example, in 1933 the ratio of horses to people was one horse to 4.7 people; in 1934, one to 5.9; and in 1935, one to 7.5, indicating a decrease in horses for the three years, whereas the number of cows has considerably increased. For example, in 1933 there was one cow to 6.6 people, but in 1935 the number of cows increased to make the ratio one to 4.2. If horses are considered a luxury, then Pisté is less wealthy in 1935 than it was in 1933. This may be directly associated with Carnegie Institution's work at Chichén Itzá, since little excavation was done in 1934 and 1935, and for this reason the people have shifted toward the raising of cattle. Comparing these figures with statistics from the towns of Chan Kom and Xochenpich, it may be noted that in 1935 both of the towns had more horses per one person than did Pisté, and Chan Kom had many more cows than did either Pisté or Xochenpich. The figures are as follows: Chan Kom, one cow to 1.4 people; Xochenpich, one cow to 3.8 people; Pisté, one cow to 4.2 people. From the Pisté records the ratio of pigs to people was one to 1.1 in 1933, one to 1.2 in 1934, but in 1935 the number of pigs had decreased so as to make the ratio to one to 10.1 people. The low percentage of pigs was due to hog cholera, since the ratio of pigs to people in Chan Kom and Xochenpich in 1935 was approximately that which was noted for Pisté in 1933 and 1934. Figures have also been gathered as to the ratio of turkeys, chickens, cats, dogs, goats, and bee hives to people.

10.10.

MORRIS STEGGERDA

Anthropology and Human Geography

YB 35:140-142, 1936

The Department of Genetics has continued its greatly appreciated cooperation with the Division of Historical Research by making it possible for Dr. Steggerda to continue field work in Yucatán.

Dr. Steggerda's program for comparative studies on the growth of children of different races has included measurements of some 146 Maya children, 81 of whom have now been measured five or six consecutive years. Forty-six observations have been made on each of these children each year. During the past year Dr. Steggerda has attempted to secure a large number of additional children of each age, in order to establish standards to which growing children may be compared for individual differences. At present, individual growth curves for 15 of these observations have been plotted for each of the 81 Maya children measured five or six years. Next will follow a comparison with other races. In this connection it may be said that for all ages from six years to adulthood the Maya average about 10 cm shorter than Navajos. Thus, the characteristic of shortness already exists at the age of six, perhaps even earlier, and persists throughout the growing years. Data for ages below six are being accumulated.

The study of tooth decay among the Maya has now been completed. The Maya have excellent teeth. Evidence for this statement is based upon comparative studies made by Dr. Steggerda on Navajo Indians, Jamaica Negroes and Dutch whites. For the age group between six and 10 years there were 16 times more individuals among Dutch whites affected by tooth decay than among the Maya, and in the 11 to 15 year class there were eight times more whites than Maya. Considering the percentage of carious to sound teeth in the two groups, the whites were 21 times higher than the Maya in the six to 10 year class, six times higher in the 11 to 15 year class, and nine times higher in the 16 to 20 age group, in which group all milk dentition had been lost.

One problem, which concerns all anthropologists, is the age and cause of death in a population. There are records in Yucatán which give date and cause of death, and a stated age for each entry. The recorded ages, however, are nearly all in round numbers. An earnest effort was made this year to determine the degree of error in the stated age in the Yucatán death records. This was done by securing the birth record of as many death entries as possible. Thus in the 35 to 39

year age group the fluctuations from the correct age ranged from minus 14 to plus nine years in error. Only four out of 20 entries were given accurately. It is hoped that in another year enough figures for all ages will have accrued to indicate the statistical error in the Yucatán death records. If this can be determined we shall be able to state accurately the life span of the Maya.

Dr. Steggerda's agronomic survey has reached the point where it can be said that the average size of 442 farms (milpas) in the Chichén Itzá area equals 97 mecates or 9.6 acres [0.04 sq km]. This average was calculated over a four year period during which weather conditions caused fluctuations in milpa size, making the average more significant. In the fertile Puuc area 122 milpas near Pencuyut average only 4.5 acres [0.02 sq km], which is less than half the size of those near Chichén Itzá. The data also show that the first-year milpas are approximately 15 to 20 percent larger than second year milpas.

Estimates of corn yield in the Chichén Itzá area were obtained from 111 farms. The estimated average yield was 0.72 cargas per mecate. First year milpas yield 0.80 cargas and second year 0.63 cargas per mecate. Realizing that these figures were based on very rough guesses, Dr. Steggerda enlisted the cooperation of some of the most influential farmers in weighing and measuring all corn produced on a given field. When this was done the figures increased tremendously; for example, on four such farms the yield was found to be in one case 1.3 cargas per mecate, in two cases 1.5 cargas, and in the fourth 1.7 cargas per mecate or, in American terminology, an average of 25.3 bushels per acre [4046.9 square m], which compares favorably with the average yield throughout the United States. The results, however, are inaccurate, since the length of the measuring rope with which the ground laid out varies from 19 to 23 m. In another year it is hoped eliminate this error.

The results of experiments on soil deterioration are accumulating. At present, after four years, there seems to be as much fluctuation in amount of nitrogen, carbon, calcium, phosphorus, etc., in the control plot, which in uncultivated bush, as there is in the other plots, one of which is in active corn production and the other reverting back to bush. This fact lends evidence to the theory of weed competition recently advanced by Kempton of the United States Department of Agriculture.

With the cooperation of Mr. Ralph Roys, Dr. Steggerda selected from Roys's *Ethno-Botany* 30 plants which were most commonly used as medicine by the Maya in the eighteenth century. Roys states in his introduction that many of these usages have altered little since the sixteenth century, when Maya medicine was

still unaffected by Spanish influence. From the writings of three present-day Yucatecan doctors and verbally from four Indian herbalists from different pueblos, the present usages of plants in question have been learned. Twelve of the 30, or 40 percent, of which have been scientifically identified, have been employed consistently over several hundred years by the Maya for specific ailments. In the other 18 cases there was confusion in vernacular designations, the same common name being applied to different plants, thus Roys's citation may apply to species other than those under consideration. Five of 30 plants put to service in colonial times are not used by in herbalists, and two now consistently employed for specific complaints formerly used for other diseases. Although it has been stated that there is but little pharmaceutical science involved in the medicinal usages of plants by primitive people, it is nevertheless interesting that confidence in therapeutic value of 40 percent of the group should have persisted, nearly four centuries.

10.11.

MORRIS STEGGERDA

Anthropology and Human Genetics

YB 36:150–151, 1937

Dr. Steggerda's studies of the living Maya of Yucatán, which have been made possible by cooperation of the Institution's Department of Genetics, were continued.

Dr. Steggerda has previously reported a lower incidence of dental caries in the Yucatán Maya and the Navajo Indians than in Dutch whites in Michigan and in other white groups reported in the United States. This season Dr. T. J. Hill, of Western Reserve University, checked Dr. Steggerda's findings in Yucatán and in addition showed that the percentage of Maya Indians free from *Bacillus acidophilus* was considerably higher and the number of these bacteria in individual mouths was relatively lower than for whites in the United States. These results are extremely important in that they support the theory that tooth decay in humans is directly related to the presence of *B. acidophilus*. The diet of these Indians, previously shown to be largely carbohydrate, should not deter the growth of these organisms.

The 150 Maya children who constitute part of the problem on comparative growth in different races have

now been measured for seven consecutive years. Since many are now married and have children of their own, Dr. Steggerda feels that the field work is now complete and the data are ready for analysis.

The agricultural survey of the Maya will require one or two more seasons; however, at present it is possible to supply the following facts: The average, size of Yucatán milpas is 99.23 mecates or 9.8 acres [0.04 sq km]. The yield per micate is still indefinite, but it may be fair to consider it as one carga per micate, or 17 bushels per acre [4046.9 square m]. An average family of five individuals consumes 6.65 pounds per day or approximately 64 bushels per year. It was determined that it takes nine hours on the average to produce one bushel.

Family statistics are also available showing that the average number of children per woman whose reproductive life is complete is 8.14. The reproductive span for 39 women was found to be 16 years. The average age of Maya girls at marriage is 16.3 and their age at the birth of their first child is 17.8. The average interval between births is 27 months.

In last year's report were discussed the medical usages, by the colonial and modern Maya, of 25 Yucatecan plants. This year 100 additional medicinal plants were studied. Dr. Steggerda's tabulation now also lists other plants used by the modern Maya for food, lumber, and miscellaneous purposes.

Cooperative projects dealing with problems on the psychology of the Maya are in progress.

10.12.

T. D. STEWART

Anthropometry of the Highland Maya

YB 46:195–197, 1947

The late Dr. Aleš Hrdlicka had planned to visit Guatemala in December 1943 to take measurements and observations on the highland Maya, but he died in September of that year. His successor in the curatorship of the Division of Physical Anthropology, United States National Museum, Dr. T. D. Stewart, finally undertook this work during the first three months of 1947. His trip was made in cooperation with the Guatemalan government and under the program for co-operation with the American republics through the State Department and the Smithsonian Institution. In addition to

studying the living, Dr. Stewart examined the available prehistoric skeletal remains, especially those recovered at San Agustín Acasaguastlán (Smith and Kidder 1943), at Kaminaljuyú, and at Zaculeu.

The main objective of Dr. Stewart's trip was to obtain information about the highland Maya which would enable him to make comparisons with the lowland Maya of Yucatán. These two groups, although rather widely separated geographically and exhibiting differences in material culture, nevertheless belong to the same linguistic stock. According to J. Alden Mason (1940:70), "The Maya stock is unusually homogeneous both as regards geographical location, and linguistic differentiation. It is really too unified for even the major divisions to deserve the rating of 'families,' and many of the so-called 'languages' differ only dialectically." Since language is fairly resistant to change (more so than material culture), considerable interest attaches to the question whether this linguistic homogeneity reflects a similar status in physical type.

Anthropometric records on the Maya Indians of Yucatán, obtained through the interest of the Carnegie Institution by G. D. Williams and Morris Steggerda, have already been published (Steggerda 1932, 1941; Williams 1931). For the highland groups of Guatemala, on the other hand, only two anthropometric studies are on record, one by Oliver La Farge and Douglas Byers (1931) and the other by Ada d'Aloja (1939). Neither of these Guatemalan studies, which are themselves not very well known, includes comparisons with Yucatán.

Dr. Stewart undertook the collection of data that would supplement those already available and at the same time allow their fuller interpretation. Since in Guatemala the municipio, being endogamous, is the basic unit for ethnic study, as Dr. Sol Tax (1937) has shown, Dr. Stewart restricted his study to two municipios within one linguistic subgroup, the Cakchiquel. First at Sololá, Department of Sololá, and later at Patzún, Department of Chimaltenango, he obtained comparable series of males, 82 and 72 respectively. At Patzún, moreover, he obtained a series of 35 females. All together this is the largest series from one highland linguistic group thus far studied.

In addition to the routine anthropometric measurements, observations, and photographs, the records

obtained this season include blood groups (A, B; M, N), taste sensitivity to phenyl-thiocarbamide, palm- and fingerprints, and hair samples. Arrangements have been made for Dr. William C. Boyd, of Boston University School of Medicine, to analyze the blood groups and taste records, and for Dr. Harold Cummins, of Tulane University Medical School, to analyze the dermatoglyphics.

Preliminary inspection of the anthropometric records indicates that the Cakchiquel are lighter complexioned, slightly lighter in weight, longer headed, narrower-faced, and broader nosed than the lowland Maya of Yucatán. Also, there are some significant metrical differences between the samples from Sololá and Patzún, a fact which suggests that, as suspected, inbreeding is producing local varieties in the highlands.

In his examination of the skeletal remains Dr. Stewart gave special attention to evidences of cultural practices, such as artificial deformation of the head and dental mutilation. The former, almost universal in the collections examined, mostly consisted in flattening of the occipital in the vertical plane ("cradleboard deformity") combined with frontal flattening. Previously this type had been reported only from Tajumulco (Stewart 1943). In other cases, especially at Kaminaljuyú, only frontal flattening was present. Also, at Zaculeu some evidence of the so-called "lambdoid" deformity was found in skulls from the most recent tombs.

As for dental mutilations, five examples of filed teeth were observed in the Zaculeu collections. One of these is a new type, or at least not included in the Borbolla key (Rubin de la Borbolla 1940), whereas the others are types known from elsewhere in the Maya area.

It is regarded as desirable that the experience gained in this successful first season be utilized for the extension of these observations elsewhere. For example, it is important to learn to what extent in the highlands the barrier of language is an aid in the formation of physical types. In this connection the Quiché, neighbors of the Cakchiquel, or the Mam, neighbors in turn of the Quiché, should be more fully studied. If the records are made by one observer, moreover, they will be more uniform and less subject to multiple personal biases.

11.1.

J. ERIC S. THOMPSON

Excavations in British Honduras

YB 33:95–98, 1934

As a joint project of the Field Museum of Natural History and Carnegie Institution of Washington, Mr. J. Eric Thompson visited northern British Honduras in the winter of 1934. The purpose of the expedition was to continue promising earlier investigations made in this region by Mr. Thompson, one of the specific objectives being to follow certain clues indicating the possibility of recovering archaeological evidence bearing on the much debated question of the correlation between Maya and Christian chronology.

Recent study of this problem strongly suggests that one of two proposed correlations is correct. According to that of Spinden, the Maya date 10.3.0.0.0, which is the latest so far found at Old Empire sites (Uaxactún, Naachtún, La Muñeca) and which is therefore thought to register a year shortly before the close of the Old Empire, corresponds to 639 A.D. Under the alternative Goodman-Thompson correlation, 10.3.0.0.0 should be 260 years later, or 899 A.D.

Settlement of the correlation problem is eminently desirable, for as long as so serious a difference exists

between the two most generally approved systems, it is impossible to take full advantage of the remarkably complete chronological documentation of early Maya sites. Dates in the Old Empire Long Count are, it is true, accurate in relation to each other, and therefore correctly express lapses of time during the era in which they were in use. But until we are able to relate them, in terms of the Christian calendar, with the abbreviated dates of the New Empire, we can not properly interpret evidence bearing on the extremely important period of the abandonment of the southern cities and the rise of the great late centers of northern Yucatán. If the Spinden correlation be correct, one must allow, for the phenomenon of transition, over 250 years more than is required by that of Goodman and Thompson. And a full quarter of a millennium is a great amount time, when one is attempting to evaluate historical events or cultural changes

In addition to its large significance for Maya research, the correlation of Old Empire with Christian dates is necessary for proper understanding of what

took place in Middle America as a whole. The Maya calendar offers the only absolute chronological yardstick we are ever likely to have for measuring the growth and spread of cultures in that field. And unless we can be certain as to where that yardstick should be laid, it is of relatively little use.

Attempts to solve the correlation problem have, to date, been founded upon two sorts of evidence: historical (post-Conquest records, Maya and Spanish), and astronomical (internal evidence from the monuments and codices). The archaeological attack has not yet been seriously undertaken. This holds considerable promise of success, for if it be true that either the Spinden system or that of Goodman-Thompson must be correct, it seems certain that intensive analytical study of Maya remains with thoroughgoing comparative work upon adjacent and allied cultures will enable us to decide whether the 250 year period should or should not be interpolated. Judgments as to short time-intervals can naturally not be made on the basis of archaeological findings; but they should certainly permit us to deal confidently with a span as long as the one in question.

The following of an archaeological clue bearing on correlation was, as has been said, one of the objectives of Mr. Thompson's work in British Honduras. The Field Museum expedition of 1931, under his direction, had revealed at San José, west of Belize and about 12 miles [19.3 km] from the Guatemala border, ruins containing pottery of non-Maya ancestry (though probably of Maya manufacture) which appeared to be of late date, yet which seemed to be associated with typical Maya wares of the Old Empire. Could this association be confirmed, it would of course argue for the correctness of the shorter Goodman-Thompson correlation. The excavations were accordingly planned and carried out with a view to recovery of all possible stratigraphic data.

The ruins of San José consist of two ceremonial plazas of the usual Maya; that is, they are flanked by a series of mounds, some of which are surmounted by stone-vaulted rooms. The largest mounds attain heights of to 40 feet [12.2 m]. In addition to the main groups there are two smaller consisting of low house mounds facing small courts, and a series of scattered mounds and structures including a ballcourt. There is only one and that is plain.

The investigation resulted in establishment, on stratigraphic evidence, series of five sequent ceramic periods designated San José I to V. The earliest, San José I, was but sparsely represented. Its pottery seems to show affinities with the wide-spread, and evidently important, but not yet accurately located or described, early complex at present known as the "Q" culture. San José II wares bear likenesses to those of early

Holmul, Uaxactún I and, possibly, Teotihuacán II periods. The principal San José III ware can be correlated with certain pottery from the Mountain Cow region of British Honduras, which, from associated finds, is perhaps relatable to Holmul V. San José IV represents, apart from olla ware, a break from San José III, but may possibly be correlated with Uaxactún III, but is possibly later than Holmul V. San José V is clearly a lineal descendant of IV. Several IV wares continue almost unmodified to the end of San José V. This suggests a short time-interval.

If one can link San José III with Holmul V, and if Holmul V has been correctly assigned to the close of the Old Empire, then the fact that San José V was apparently a short period closing not long before the Conquest would indicate that possibly there is no room for the 260 extra years required by the Spinden correlation, but rather that the Goodman-Thompson dating may itself be actually too early, and that 10.3.0.0.0 may have fallen less than 500 years before the arrival of the Spanish.

So little is really yet known of Maya ceramics that one can not make categorical statements but it would seem highly improbable that all architectural and ceremonial activities in the Petén ceased 900 years before the Spaniards came. The answer to this question might be supplied by the ceramics of Tayasal. Should Yucatecan pottery be found there in quantities in association with that characteristic of the close of the Old Empire, one could postulate that the Old Empire persisted up to the time of the migration of the Itzá in the late fifteenth century.

Thus, while no conclusive determination was made of the length of the period of transition, the classification and sequential ranking of the local wares and the linking with them of various foreign types constitute a very important advance in the study of Maya ceramics.

At present it seems probable that San José was founded at the beginning of the Old Empire, and that the region was continuously occupied until shortly before the coming of the Spaniards. Period IV witnessed the greatest building activity. During Periods IV and V trade with other areas was at its height. In V deposits, pottery spindle-whorls occur for the first time; two of these are of Huasteca or northern Totonacan origin. At the same time marble vases were being imported, perhaps from the Ulúa valley in Honduras; as well as typical "paint-trickle" decorated ollas from Yucatán, ollas from Oaxaca and finely carved pottery. Strangely enough, no Plumbate Ware appeared. In general, Uaxactún ceramic influences seem to have been more potent than those of Holmul, although Holmul is much nearer and practically lies between Uaxactún and San José. In the same way, San José should have cut off the

flow of Holmul influence to Santa Rita, which lies beyond and which shows many Holmul traits.

Such paradoxes as the above, encountered at the beginning of an investigation, are temporarily confusing; but the very fact that a ceramic situation is complex shows that many types were evolved and that trade, or at least interinfluence, was strong. Such conditions result in deposition of remains which, however puzzling at first contact, most amply repay intensive study. Mr. Thompson's earlier work in the El Cayo district and the past year's excavations at San José indicate that British Honduras, while lacking the spectacular ruins of Guatemala and Yucatán, is a very promising field for further investigation.

11.2.

J. ERIC S. THOMPSON

Reconnaissance and Excavation in British Honduras

YB 37:152–153, 1938

Early in 1938 Mr. Thompson made a reconnaissance of the northern part of the Great Southern Pine Ridge of Central British Honduras in an endeavor to find traces of a pre-agricultural horizon. This elevated broken area, the flora of which is pine, grass scrub oak, and a type of palmetto, is quite unsuited to maize cultivation, yet it was known that a number of cairns, consisting of heaps of stones around slate shafts, were situated on many of the highest points. Excavation of these produced negative data as to when they were erected. No caches were found, but a few sherds including incensario fragments and a pressure-flaked flint point among the stones pointed to their use during the Maya period, presumably in the same way that mountain tops were used as shrines by the Chols and highland Maya into colonial times.

At the close of this reconnaissance a small outlying group at the ruins of Benque Viejo (Xunantunich) was excavated. Previous work at San José and Mountain Cow had revealed close similarities in the earlier ceramic phases, but rather marked divergence in the later phases, Mountain Cow late pottery resembling that of Uaxactún more closely than that of San José. Since the connections between late San José and late Uaxactún (Tepeu Phase) pottery were largely indirect, and dependent on Mountain Cow, it was thought that study of late periods at a site about halfway between

San José and Mountain Cow might clarify problems of contemporaneity. Benque Viejo was chosen as being very accessible and roughly equidistant from the three sites.

Excavation yielded three Sequent phases, correlatable with San José III, Transition III-IV, and close of San José IV, and a fourth, unstratified, corresponding to Uaxactún 1a (Mamom). Since sherds from Benque Viejo of forms occurring in Uaxactún Ib (Chicanel) and Uaxactún II (Tzakol), which in turn correspond to San José I and II, are in the Peabody Museum, Harvard University, a complete series for this site now exists.

In the phase correlatable with close of San José IV, the resemblances to certain Tepeu features are more marked, and correspondences with Mountain Cow are close in all three phases. The last Benque Viejo phase shares with close of San José IV and San José V the absence or extreme rarity of polychrome pottery and introduction of carved pottery.

Excavation at Benque Viejo has, therefore, helped to clarify relations and divergences between San José, Mountain Cow, and Uaxactún, and confirms the disappearance of polychrome pottery toward the close of occupation already reported for San José.

At the close of the season Mr. Thompson proceeded overland from Benque Viejo to the northwest of the colony to visit a site reported by chicleros. This, named La Milpa from a nearby chicleros' camp, lies about 7 miles [11.3 km] southwest of Warree Camp close to the junction of the Victoria Creek with the Bravo River.

The numerous mounds, pyramidal and razor-backed (probably collapsed ranges of vaulted buildings), are in detached groups and are probably of early Petén masonry style since no dressed stone was observed during the two days spent at the ruins. Twelve stelae had stood in front of various mounds on the east side of the main plaza. All were extremely weathered and most had fallen face upward. Apparently three were plain; the rest carved. Only one (Stela 7) was sufficiently preserved to yield a date. This proved to be 9.17.10.0.0, 12 Ahau 8 Pax recorded by an Initial Series on the north side, the Calendar Round being repeated on the front. Altars stood before some stelae. Two mounds, which seemingly formed a ballcourt of the sloped-wall type and with east-west axis, are situated on the east side of the plaza.

Mr. Thompson also visited Guatemala City to examine pottery from Uaxactún and Kaminaljuyú, and to discuss ceramic problems with the Chairman and Mr. R. E. Smith. He also proceeded to Copán, where he was able to recover two more dates. A stone incensario, part of which was found in the shaft of Temple 11, yielded (9.17.2.0.0) 5 Ahau 3 Cumhu reached from an earlier 9.16.13.0.0, and from a jamb of Temple 11 a Calendar Round, date 3 Cib 7 Pop, which is pretty surely 9.17.0.0.16, 3 Cib 9 Pop, was recovered.

12.0. BAKING POT

12.1.

OLIVER G. RICKETSON

*Report on the excavations at Baking Pot,
British Honduras*

YB 23:219–221, 1924

The excavations carried out during the season of 1924 at Baking Pot were under the direction of Mr. Oliver Ricketson Jr., who sailed from New Orleans on February 10, proceeding to Belize, British Honduras, where he accompanied Mr. Blom and Mr. Amsden to the ruins of Uaxactún, Guatemala, returning immediately to Belize to outfit and provision.

Baking Pot lies on the south bank of the Belize River, six miles by land easterly from El Cayo. The ruins consist of two distinct groups lying in a large clearing, belonging to Mr. Arthur Williamson of Belize, to whom the expedition is greatly indebted for many courtesies.

Dr. Thomas Gann, by a careful study of Cogolludo and Villagutierre Sotomayor, and aided by a first-hand knowledge of the topography and drainage of the country traversed by Avendaño, Fuensalida, and Orbita, has concluded that the Tipú mentioned in these accounts must be the ruins located at modern Baking Pot, since no others in that vicinity fulfill the require-

ments as to size, location, and stated distances. As Tipú was the location of the first Franciscan mission in what is now British Honduras, it was hoped that the discovery of its remains might positively identify the site as Tipú. The almost innumerable small mounds that dot the whole clearing, however, uniformly offered such a smoothly rounding appearance that a far more exhaustive study would be necessary to determine the actual presence or absence of such a mission.

Excavation started March 23, four different sites being examined. The first site was a small house-mound to the north of Group 1, consisting of a rectangular platform of faced stone. The finds were coarse sherds, broken granite mauls, and a few flints.

The second site excavated was the top of the most prominent pyramid (Pyramid B) in Group 1. This group lay with its long axis east and west, a quarter mile to the north of Group 2 and 250 m from the nearest bank of the river. It consisted of three built up plazas, Plaza 1 being the lowest and westernmost, Plaza

2 (separated from Plaza 1 by the centrally located Pyramid B), being the medial one in both position and elevation, and Plaza 3 being the easternmost and highest. Both axes of the top of B were trenched to a depth of over a meter. No worked stone and only a very few natural rocks were found. Sherds were conspicuously absent.

Excavations at the third and fourth sites were started simultaneously. One of these was the top of a small pyramid (E) placed centrally on a mound running north and south between Plazas 2 and 3. It was composed entirely of unworked limestone and limestone marl. A cache of nine eccentric flints and two small jade pieces was uncovered.

The last site to be described is a steeply sloping, circular mound (G), lying on the northern edge of the Plaza 3, 4.5 m high and 26 m in diameter. Excavation revealed a rectangular retaining wall of faced limestone with slight lateral projections, the wall curving up from each corner (where the average height was less than one meter) to the midpoint of each side (where the average height was 1.8 m). On the south side close to the southwest corner, but lying outside the retaining wall, three skeletons were found, all lying parallel to the wall, Burial 1 lay face up, was male, and lacked the right arm, the pelvis, and both legs; the burial objects were a piece of antler, a corn grinder, and grinding stone. Burial 2 was also face up, the right leg fully extended, but flexed at the hip so that the foot lay above the head; the right femur's greatest length was 43.6 cm. The left leg was missing, though the head of the femur was in the acetabulum; no burial objects were found. The head of Burial 3 lay directly beneath the pelvis of Burial 2. It showed marked fronto-occipital flattening, and was the only cranium unbroken. All three burials were simple inhumation.

The mound was then trenched from the south side to the center. Inside and above the retaining all another wall was encountered. This was also of faced stone, and sloped upward from the corners to the mid-

point. Lying parallel to this wall and just outside it, another skeleton was uncovered, face down, simple inhumation, and no burial objects.

Continuing the trench to the center, Burials 4 and 5 were encountered, no. 4 lying directly over no. 5, at a depth of 1.4 m. Both lay face down, head to the south, as did all of the other eight skeletons found at the top.

Just beyond Burials 4 and a sepulcher was found, lined with faced stone and covered with flat slabs of rock. In endeavoring to trench around the east side, seven skeletons were uncovered. Of these the following peculiarities may be noted: no. 7 had a deformed left humerus (25.3 cm as opposed to 31.6 in the right) and an enlarged head and great tuberosity on the left femur; no. 8 had five and one-half of the upper front teeth deeply filed; no. 11 was directly superimposed on no. 13, the latter, besides other objects, having a large and deformed antler, drilled and grooved, under the mandible; no. 12, directly superimposed above no. 14, had the upper front teeth filed as in the case of no. 8. No. 14 still retained the deciduous teeth; its cranium lay below the pelvis of no. 12; the sciatic notch of the latter enabled identification as a female.

Burial 15 occupied the central grave of stone. The upper five front teeth were inlaid with circular fillings of iron pyrite on their anterior surfaces. There were two three-legged pots, that at the head being incised with a plaited design, the one at the feet being plain; both were black. Other burial objects were five jade beads, two jade ear-plugs, and several pieces of carved bone and shell. The bones were badly decayed, yet the left shaft of the femur was sufficiently preserved to show clearly lesions closely resembling the involucre of syphilis, if not syphilis itself. Many of the 12 crania obtained when assembled will undoubtedly show marked fronto-occipital flattening.

Work was concluded May 31 and Mr. Ricketson proceeded to Chichén Itzá, returning to the United States in July.

13.0. PUSILHÁ

Pusilhá is the southernmost site in Belize where hieroglyphic texts have been identified, and is located a short distance from the Guatemalan border. Since it was discovered in 1926, 26 sculptured stone monuments (21 stelae, two fragments, and three altars) have been found. All of these monuments were located in the stelae plaza.

13.1.

SYLVANUS G. MORLEY

Report on the Pusilhá Expedition

YB 27:318–320, 1928

The ruins of Pusilhá are located in the extreme southern part of British Honduras, about a mile [1.6 km] east of the Guatemala frontier, on a point of land be-

tween the Pusilhá and Machaka Rivers, which unite here to form the Mojo River. Hills surround the site on all sides, enclosing a valley of very great fertility; even today the rain fall is so excessive, probably being between 140 inches [355.6 cm] and 150 inches [381 cm], that it is possible to raise three crops of corn a year.

There are the remains of an ancient bridge over the Pusilhá River, two stone piers, perhaps 20 feet [6.1 m] high 30 feet [9.1 m] long and some 30 feet [9.1 m] apart, one on either side of the river. The sides of these piers, facing upstream, have been given concave outlines so that logs coming down at high water and striking them would be diverted toward the middle, and thus more easily pass beneath the bridge without blocking (Joyce, Clark, and Thompson 1927:315).

The word *pusilhá* means in Maya, *pusil*, stagnant; *ha*, water, that is, stagnant water, a name possibly derived from some fancied characteristic of the river of the same name which flows by the group.

Pusilhá was discovered during the summer of 1927 by Mr. James R. Mason, in charge of the mahogany

operations of Mr. Lee Pierce of Punta Gorda. Mr. J. Eric S. Thompson, of the Field Museum of Natural History, Chicago, visited the site a few months later and deciphered four of the Initial Series there, those on Stela D (first Initial Series), K, M and O (Thompson 1928:95).

In December 1927 and again in March 1928, Dr. T. Gann visited Pusilhá on behalf of the British Museum, spending five weeks at the site during his second visit and removing four of the monuments, Stelae M, O, P and Q, to Punta Gorda for transportation to the British Museum. On his second visit Dr. Gann deciphered three additional dates, Stela H (first Initial Series), Stela Q and Stela Y (first Initial Series).

Dr. Morley was at Pusilhá from May 5 to May 7 and deciphered five other dates as follows: Stela D (second Initial Series), Stelae E and F, and Stelae H and Y (second Initial Series). A complete list of the dated monuments at Pusilhá, arranged in their chronological sequence, is given in the following table:

Table 13.1.1. Calendrical Decipherments, Pusilhá.

<i>Monument</i>	<i>Maya Date</i>	<i>Christian Era (A.D.)</i>	<i>Kind of Date</i>
Stela O	9.7.0.0.0	314	Initial Series
Stela Q	9.8.0.0.0	334	Initial Series
Stela F	9.9.13.0.0	367	Period Ending
Stela D	9.3.0.0.0	334	Initial Series*
Stela D	9.10.15.0.0	388	Initial Series
Stela Y	9.7.0.0.0	314	Initial Series
Stela Y	9.10.15.0.0	388	Initial Series
Stela H	9.11.0.0.0	393	Initial Series
Stela H	9.7.12.6.7	326	Initial Series
Stela K	9.12.0.0.0	413	Initial Series
Stela M	9.14.0.0.0	452	Initial Series
Stela E	9.15.0.0.0	472	Initial Series

* The katun coefficient in this Initial Series is recorded as three. Katun 8, however, is clearly recorded in Glyph A8, and Glyph A7b may represent its corresponding month position, 3 Chen. In any event the contemporaneous date of Stela D is not the first but the second Initial Series, 9.10.15.0.0

There are 20 monuments in the principal plaza at Pusilhá, all but two of them (Stelae U and Y) on the south side in front of Mound 1. Of these, the dates of nine have been deciphered. Three others, Stelae N, P, and U, formerly had Initial Series, a fact proved by presence of the accompanying Supplementary Series in each case, but they are now too effaced to permit decipherment. The Supplementary Series of Stela P indicates that its Initial Series may have been 9.13.0.0.0. The remaining eight monuments, Stelae A, B, C, G, L, R, S, and T, have their inscriptions entirely destroyed. Indeed in the cases of most of these monuments, the only parts which have escaped the ravages of time and weather are the butts, the upper parts having com-

pletely eroded away. There are 14 Initial Series and one Period Ending date.

There is not a single standing stela in the city, most of them having fallen backward instead of forward, thus preserving the inscriptions on their backs, rather than the human or divine figures, which had been carved on their fronts. Only one monument, Stela C, has a well-preserved figure; this shows a gorgeously dressed individual clasping a double-headed ceremonial bar diagonally across his breast.

The dates at Pusilhá indicate a fairly early Old Empire site, founded some time toward the close of the Early Period. Stela O, stylistically as well as chronologically, is the oldest monument, the early technique of its glyphs, show irregular outlines agreeing with the early date recorded upon it. Six of the nine dated monuments (Stelae O, Q, H, K, M and E) were erected on katun-endings; two (Stelae D and Y) on hotun-endings, and one (Stela F) on an oxlahuntun-ending. It is to be supposed that some of the other monuments, the inscriptions of which are effaced, filled the existing lacunae in the chronological sequence.

Stelae D, H and Y have a characteristic shared by but two other monuments in the whole Maya area: Stela 1 and 6 at Macanxoc-Cobá [Chapter 34.1], that is each has two Initial Series instead of one, the second Initial Series in each case, following the body of the text some distance after the first Initial Series. As the Initial Series were originally so named by A. P. Maudslay, the English explorer, because of the fact that they always stand at the beginning of inscriptions where they appear (Maudslay 1889–1902:1:40), the five cases given above are the only examples of their kind now known in the *Corpus Inscriptionum Mayarum*.

Stela K at Pusilhá shares with Stela 4 and Altar I at Copán and Stela 10 at Tikal an even greater distinction, these four monuments being the only ones known where the Initial Series stands elsewhere than at the beginning of an inscription. The Initial Series on Stela K at Pusilhá stands at the top of the third and fourth columns of glyphs from the left, instead of the first and second, or the first alone, the position elsewhere (Morley 1920:190–193, 356).

The latest date at Pusilhá, 9.15.0.0.0, on Stela E, indicates that the city was occupied, at least down to the beginning of the Great Period. But how much longer it continued to be occupied, before it was abandoned, is a matter of conjecture, failing the positive evidence of dated monuments. It is not improbable, however, that Pusilhá ceased flourishing as a center of population sufficiently important to erect monuments commemorating the katun-endings, well before the beginning of Baktun 10¹ and by 10.3.0.0.0 when the last monuments seem to have been erected in the Old Empire region.²

NOTES

1. The latest date near Pusilhá is 9.18.5.0.0 on Altar 1 and Cancuen, some 30 miles [48.3 km] westward in Guatemala, discovered by the First Central American Expedition in 1915 [Chapter 1.3].

2. Stela 10 at Xultún [Chapter 1.8] and Stela 12 at Uaxactún [Chapter 1.10] are the two latest Old Empire monuments known; both of them record this date, it probably had been completely abandoned.

14.0. SAN JOSÉ

J. Eric S. Thompson made an extensive study of San José, what he considered to be a small ceremonial center located 35 km northeast of the site of Holmul. The San José site has a plaster-lined aguada, or water hole, four small plaza groups of mounds, a ball court, vaulted architecture, and plain stelae.

14.1.

J. ERIC S. THOMPSON

Exploration in Campeche and Quintana Roo and Excavations at San José, British Honduras

YB 35:125–128, 1936

In an endeavor to learn something of the archaeology of the region directly east of that explored by the

Campeche expedition of 1932, 1933, and 1934 [Chapters 15.1 to 15.3], an expedition left Chichén Itzá at the end of February 1936, with Mr. Thompson in charge, Mr. J. C. Harrington, surveyor; Mr. Conrad Kratz made rubbings of inscriptions and graffiti. Principal objectives were the collection of epigraphic material and of such other data as might throw light on the position in Maya history of the peculiar architectural styles known as Río Bec and Ramonal, both of which find very close parallels in the architecture of the Chenes region, and to a lesser extent in that of the Puuc and that of the so-called Renaissance style at Chichén Itzá and elsewhere. On the other hand, there are also certain parallels between Río Bec sites and cities of north-eastern Petén, particularly La Honradez. On the strength of the above resemblances it has been suggested that Río Bec and Ramonal architectural styles are transitional in time between the so-called Old and New Empires. An alternative theory that the sites are transitional merely in geographical sense has also been advanced.

Three new sites, Las Escobas (18 degrees, 21'.6, 89 degrees 20'.6), No Te Metas, and San Lorenzo, possessing architecture in these two styles, were discovered. Unfortunately very little ceramic material was recovered. Sherds from under the floors of the buildings would undoubtedly have solved the problem few sherds, however, were found at terrace edges, and these should eventually yield evidence on the age and cultural relationships of the ruins. A considerable amount of information on architecture and masonry was obtained.

El Palmar, a large site situated at 18 degrees, 5'.0, 89 degrees 20'.6, detained the expedition for three weeks. This city had been built around two lakes, one of which had in its center, a small island bearing the ruins of a small structure and a plain stela. Mr. Harrington mapped an area 900 m north and south, by 660 m east and west.

Every superstructure had fallen, but fragmentary, walls showed that masonry was unsquared and unfaced. It had been laid in and covered, masses of mortar. This masonry contrasted sharply with the very carefully faced stone veneer found on buildings of the Río Bec and Ramonal styles. The collapsed state of the superstructures of El Palmar is probably to inferiority of construction, since the large areas of exposed mortar offer ready lodgement for vegetation. Forty-four stelae and several round altars were found at El Palmar, but owing to the extreme softness of limestone from which they had been hewn, and the very low relief, little carving was preserved. Twenty-three stelae were carved, five plain, 16 so weathered that it was not possible to say whether or not they had once been sculptured. A peculiar feature of the inscriptions was the apparent absence of Initial Series. In those cases in which glyphs were legible, there were certainly no Initial Series, while in all other cases glyph blocks were too few to have recorded dates by this method. Period ending dates recovered were: 9.14.0.0.0?; 9.14.10.0.0; 9.18.10.0.0; 9.19.10.0.0; 10.2.15.0.0?. The stelae can be grouped stylistically with those of Naranjo and Calakmul, but in composition one stela, at least, resembles those of Honradez, in that the base of the design is occupied by a large mask, perhaps a link with the carved square columns of Yucatán.

Artistically, a find of outstanding importance was a cache of eccentric flints and obsidian cores and flakes from beneath a stela. One of the flints, which was executed in the same technique as some found at Quiriguá (Joyce 1933:88) was superbly chipped to represent, in profile, four seated deities.

A ballcourt, situated close to the great plaza, is of the usual early type with sloping sides. Two of the pyramidal substructures were of very considerable elevation: 119 and 142 feet, respectively, above the level of the aguada.

During the visit to El Palmar a new and very simple method of recording epigraphic material was evolved: the photographing in direct light of Chinese ink rubbings in position over the glyph blocks. This does away with the inevitable distortion produced when the paper sheets bearing the rubbings are removed and laid flat. The El Palmar rubbings, together with photographs of the glyph blocks taken with side lighting, constitute an epigraphic record such as exists for few Maya cities.

A stratification of pottery was encountered at El Palmar, sherds of phase characterized by basal flanged bowls being found underlying a phase in which the lateral ridged bowl predominates. The earlier phase can be correlated in form with the Tzakol Phase at Uaxactún, Holmul III (and perhaps earlier Holmul), and San José II. The later phase at El Palmar can be correlated, so far as dominant form is concerned, with San José III, which in turn appears to have been contemporaneous with Holmul V and the Tepeu Phase at Uaxactún. With the earlier pottery at El Palmar were mixed a few sherds indicating a yet earlier ceramic development, with forms partially corresponding to the Chicanel Phase at Uaxactún and early pottery at San José. On the whole El Palmar pottery seemed closer to that of British Honduras than to that of the Petén.

In the course of the field work attempt was made to collect simple botanical data. Since botanical expeditions in the Petén and contiguous areas a likely to cover far less ground than the more frequent archaeological parties the archaeologist may have to depend largely on his own observations for information on such vegetational changes as may have a bearing on cultural subdivisions of the Maya area. Naturally, the archaeologist has, as a rule, neither the time nor the training for a thorough botanical survey, but many important trees are easily recognizable, and their distributions may have archaeological importance. With this in mind, notes were kept on such features of the flora as could be observed along the trail. It was possible to note gradual changes in the vegetation as one progressed westward. For example, no cohune palms were noted until within 15 to 20 miles [24.1–32.2 km] of the Río Hondo. Similarly the all-spice tree was entirely absent in the western section, but gradually became abundant as one traversed Quintana Roo. A great belt of *cordoncillo*, *escoba* and bay leaf palm extends from north to south, its western edge roughly, coinciding with the Quintana Roo-Campeche border. Within this belt most of the Río Bec and Ramonal sites appear to be situated.

At the conclusion of the work at El Palmar, Mr. Kratz returned with surplus equipment to Yucatán via Campeche, while Messrs. Thompson and Harring-

ton proceeded via Chicchanhá to Botes on the Río Hondo, and thence a Payo Obispo to Corozal in British Honduras.

From Corozal, Messrs. Thompson and Harrington proceeded to San José, where Mr. Thompson had carried on excavations in 1931 and 1934 [Chapter 11.1]. Previous stratigraphic work at San José had revealed a sequence of five ceramic phases, which strongly suggested that the site had continued to be occupied after the supposed abandonment of the Central Maya area (shortly after 10.3.0.0.0), and that in all probability it was not deserted until the period of Mexican contact in Yucatán. The purpose of the present season's work was to amplify the ceramic and architectural information already yielded by this site, and to seek answers to certain problems which had arisen in preparation of the report upon the earlier excavations.

In the three weeks spent at San José a considerable quantity of ceramic material was obtained. cursory examination of this suggests that three new ceramic phases may have been established: by a division of the original San José I phase into two phases corresponding to the Mamón and Chicanel phases at Uaxactún (Robert E. Smith, Preliminary Shape Analysis of Uaxactún Pottery); the third, a transitional phase between San José III and IV, was only sparingly encountered in 1934, but the finds of the present season suggest that it may have to be elevated to the rank of an independent ceramic phase.

Little material of the San José II (by a regrettable oversight this phase was correlated in [Chapter 1.22] with the Uaxactún I Phase; whereas the correlation is

with Uaxactún II (Tzakol Phase), both phases having the basal flanged bowl as the most typical form) phase was encountered. This was regrettable as it had been hoped that more light might be thrown on the Teotihuacánoïd form which occurs in this phase. The 1936 excavations, however, produced additional evidence of the far-flung trade relationships of the site during San José V. New examples, of Yucatecan Slate Ware ollas, marble vase fragments and another spindle whorl, decorated with *chapopote* designs in Huastec style, were found associated with this phase. The presence of such importations, as well as of carved slate (one example), an apparently early simple silhouette form of Orange Ware (one example), many finds of Carved Red Ware, and one of copper, together with total absence of Plumbate and Carved Orange Ware, suggest that San José was abandoned shortly before the Mexican period in Yucatán, but at a time considerably subsequent to 10.3.0.0.0, if San José IV and the transitional phase following it have been correctly placed at the close of Cycle 9.

Particular attention was paid to the masonry of San José. Two definite types were identified and placed in chronological order by means of associated pottery. Details, such as the use of small potsherds and obsidian fragments in mortar, were observed, and a series of photographs of small surfaces of walls was made. Finally, there was excavated a very long and narrow building of a type not hitherto described for the Maya area. This structure, over 36 m long, yet under 4 m wide, consists of two rooms, each provided with but one doorway.

15.0. CAMPECHE

15.1.

KARL RUPPERT

Explorations in Campeche

YB 32:89–92, 1933

As result of the exploration and study of Calakmul in 1932 and reports of other sites in the same general region, an expedition spent the months of March, April and May in the exploration of south-central Campeche. Mr. Karl Ruppert, archaeologist, was in charge; Mr. John H. Denison, Jr., served as epigrapher; Mr. John O'Neill, as surveyor. The field of work was reached from Chichén Itzá via Mérida, Campeche, Canasayab, La Gloria, and Central Buenfil, which was made the base of supplies.

Messrs. Denison and O'Neill made a preliminary trip to Calakmul to take observations for latitude and longitude (N18 degrees 8.7'; W89 degrees 50' 21"). On March 10 the entire expedition left Central Buenfil for the ruins of La Muñeca, which were reached at 2:30 the same afternoon. La Muñeca is a dry camp. Anyone visiting the site, except during the rainy season should, Mr. Ruppert reports, be prepared to haul water from two to six leagues.

La Muñeca was visited in 1932 by Messrs. Ruppert and J. S. Bolles but, due to lack of time and illness, only

a sketch map of the site and a preliminary examination of the stelae and buildings were made. The latitude and longitude of the site are N18 degrees 14.7' and W89 degrees 37'. The ruins lie on two low ridges, which have their long axis north and south. Thus the city is divided into two well-defined sections, of which the westernmost contained the highest mounds and all the stelae. Nineteen stelae were found, of which eight are carved, seven carrying Initial Series dates. The earliest and latest dates for the city are 9.13.0.0.0 and 10.3.0.0.0, respectively.

The next objective was Placeres, an abandoned chicle station 7 leagues to the east, which served as base for the expedition for seven days while trails were opened and the nearby areas to the south, west and north were explored. Leaving part of the supplies and equipment at Placeres, the expedition left on March 26 for a three-weeks trip to the north and west. Stops were made at the sites of Noche Buena, Río Bec and La Hormiguero.

Noche Buena is an extensive site, a hard six hours ride north of Placeres. The buildings have almost

entirely fallen. Only in a few cases are sections of wall or arch still in position. The study of the buildings showed the incorporation of lateral wings in the ground plan in several instances. No stelae were found.

March 30 to April 7 was spent at Río Bec. This city was discovered by R. E. Merwin of the Peabody Museum some 20 years ago. Merwin's Group F and G were the only ones examined by the present expedition, attention having been confined to the area west of these groups. The site was not recognized as Río Bec until after Mr. Ruppert's return from the field, when the latitudes and longitudes were checked. They are N18 degrees 20.5' and W89 degrees 22' 4", respectively. Merwin's groups to the east of F, the nearest of which is 1.5 miles [2.4 km], were not seen. The principal structure in the western area, Structure D, Group I, with its lateral towers, was recognized as being of the Río Bec type. The masonry is the finest found, being made up of small, carefully worked stone the size of bricks. The low platforms supporting buildings have the same measurements in plan as the buildings themselves. These platforms are either plain or ornamented with colonnettes. Excavations in front of doorways did not show steps giving down from the platforms. Stucco and stone decoration covering the façades or as inset panels of geometric design was used in the ornamentation of the buildings. A type of construction not seen at other sites visited is a low rectangular platform supporting a building which extends around three sides of the platform. In the center of the open side, or sometimes in the middle of the platform, is a small masonry altar-like mound.

Hormiguero, located at latitude N18 degrees 24.0' and longitude W89 degrees 38' 35" was next visited (April 9 to 14). It is much smaller than Río Bec, but is similar in style of architecture. The use of lateral towers was noted on two structures. The principal building has a length of 47 m, a width of 10 m and contains eight rooms. In one room the ceiling was intact. The central doorway of the south façade is still supported by wooden lintels. Stucco decoration on the same façade is in a good state of preservation. Great lateral towers, with stairways as decoration only, are used as at Río Bec.

Leaving Hormiguero on May 14 the party started southward, retracing its steps to Placeres. Here it was necessary to lay over for four days while the men opened trails, and muleteers made a trip to Central Buenfil for supplies. Staying one night at the aguada of Delicia, the abandoned chicle camp of Alta Mira was reached May 20. On the way in to Alta Mira (N17 degrees 56.7', W89 degrees 31' 53") there are many mounds to be seen along the trail. Returning the next day to examine these mounds and the area lying between them and the camp, a small but carefully laid

out city was found. There were 16 stelae, of which half showed some trace of sculpture. No dates, however, were secured. Only small sections of standing walls were noted. One room, perhaps the central room of a three-chambered structure, has a portion of the arch still intact. The building carried a roof comb.

April 25 the party moved to the abandoned chicle camp of Villa Hermosa (N17 degrees 55.8' and W89 degrees 40' 35"). While waiting for the men to open trails and locate water, two days were spent exploring the many low mounds to the northeast, some of which were 1.5 to two leagues from Villa Hermosa.

The next objective was to find Nohochná, reported by C. L. Lundell as a new site in 1931. The drying up of the aguada forced the party to evacuate Villa Hermosa before the scouts had located water near Nohochná. This necessitated a detour by the way of the aguada of Monterey. Once at Nohochná, Mr. Ruppert recognized the site as Naachtún, discovered in 1922 by Dr. Morley. The party remained here from May 1 to May 12, during which time a new and more inclusive map was made. The latitude and longitude are N17 degrees 47.7', and W89 degrees 44' 22", respectively. Of the 45 stelae at Naachtún, 18 were found by Morley in 1922, eight by Lundell in 1931, and 19 by the present expedition. Only 24 show carving. The earliest Initial Series reads 9.3.10.0.0, the latest surely readable date is 9.16.0.0.0. Some of the standing buildings are of particular interest in that they resemble Maler's Temples I, II, and IV at Tikal, having three rooms, one behind the other, decorative extensions on the rear exterior wall and a niche in either end wall.

Mirador, the westernmost site, visited (N17 degrees 40'; W89 degrees 50') is perhaps that seen by Percy Madeira during his aerial survey in 1931 (Madeira 1931:121). It contains the largest and highest mounds that were encountered. There are at least nine lofty pyramids, the largest and highest of which supports seven good sized mounds, of which the largest rises not less than 20 m above the top of the great pyramid. As there was no water, it was only possible to spend one day exploring. No standing buildings were found. A small piece of sculpture, perhaps from a stela, was noted reused in the facing of a low terrace.

The final ruin visited (May 21) was Tres Marias, northeast of the chicle station of Río Disempeño. Tres Marias is a dry camp so that only, a hasty examination of the ruins could be made. The site is small and has no standing buildings or stelae. There is one plain round altar.

Between the dry aguada of Tres Marias and the ruins great numbers of small mounds were noted. They usually appear on the crest of hills. The mounds, outlined by large unworked stones, are irregular in shape and vary in size from 3 to 4 m in greatest dimension. In

height they rise 1 to 2 m. They are, often arranged around courts and may well represent dwelling house sites.

May 28 the expedition returned to Chichén Itzá, having been in the field exactly three months.

The expedition accomplished a preliminary survey of the area in southeastern Campeche from Central Buenfil to the east, north and south. Mr. Ruppert believes that since many groups of small mounds were encountered, perhaps representing dwelling house sites, there may well be large religious or civic centers associated therewith which still remain undiscovered in this section of the vast tropical forest. The area should be entered at some time when chicle operations are under way, so that the chicle gatherers may be questioned and rumors or reports of sites may be pursued. The work of the chicleros takes them off the trails in all directions through the dense bush, so that they cover the country much more thoroughly than an archaeological expedition is able to do.

15.2.

KARL RUPPERT

Explorations in Campeche

YB 33:93–95, 1934

Following the discovery of Calakmul by Mr. Lundell in 1931 and its exploration by Carnegie Institution in 1932, the need for further investigation of that part of Campeche lying between Calakmul and Uaxactún became evident. Here was a great stretch of jungle which had not as yet been examined for archaeological remains.

Since its abandonment by the Maya, this area has remained unknown except to the occasional chiclero who entered it during the rainy season to bleed the sapote trees. The chicleros have from time to time brought back reports of ruins seen during their wanderings. It was obviously desirable to learn something of the topography of the region, to study the sites and to ascertain their chronologic period. What architectural trends were manifested? Did the ruins constitute an independent group or did they show affinities to the north or to the south?

An expedition under the leadership of Mr. Ruppert explored part of the area in 1933. Hampered by scar-

city of water and by an almost complete absence of usable trails, the party covered less territory than had been hoped. However, the expedition discovered several sites, brought back reports of others and gained much useful knowledge of the trails and water holes. Valuable contacts were also made with chicle contractors working along the northern border of the region.

In 1934 a second expedition penetrated the same general area. The work was again in charge of Mr. Ruppert, with Mr. John H. Denison, Jr., as epigrapher, Fred P. Parris as surveyor. Mrs. Denison accompanied the party as assistant and also collected herpetological material. Outfitting at Chichén Itzá in Yucatán, the group was in the field from January 31 to May 8, a total of 98 days. During this time over 1,150 miles [1850.8 km] were covered, 500 [805 km] on mule back. Four major and six minor sites were discovered which, according to the practice long used by Dr. Morley, were given Maya names. Two previously known sites, Pared de los Reyes and La Muralla, were visited.

The first ruin found was Oxpemul (N18 degrees, 18.3'; W89 degrees, 47.9'). Although no buildings remained standing, the structures indicated that the city was laid out in two well-defined plazas. One group in the west plaza is very similar in plan to Group E at Uaxactún, in that a long, low mound is surmounted by three buildings, and that it is opposed, on the western side of the plaza, by a single high mound. This peculiar and possibly astronomically significant [Chapter 1.14] arrangement is also found, Mr. Ruppert points out, at a number of other Old Empire cities. Oxpemul possesses 19 sculptured stelae, of which 12 carry Initial Series dates ranging from 9.15.0.0.0 to 10.0.0.0.0.

Uaacbal, visited February 16, is a small group of mounds laid out around an extensive rectangular court. The principal building was apparently on the west side, where there rises a high mound surmounted by a roof-comb bearing human figures in stucco. There were no stelae.
